Revised Edition: April 1982

WATER QUALITY STANDARDS

ADOPTED PURSUANT TO
SECTION 62.1-44.15(3)
OF THE CODE OF VIRGINIA (1950),
AS AMENDED

COMMONWEALTH OF VIRGINIA

STATE WATER CONTROL BOARD
RICHMOND, VIRGINIA

EFFECTIVE

DECEMBER 12, 1981
(DATE OF MOST RECENT AMENDMENTS)

TABLE OF CONTENTS

INTRODUCTION

Basis and Purpose

The State Water Control Law mandates the protection of existing high quality State waters and provides for the restoration of all other State waters to such condition of quality that any such waters will permit all reasonable public uses and will support the propagation and growth of all aquatic life that might reasonably be expected to inhabit them (Section 62.1-44.2). The adoption of water quality standards under Section 62.1-44.15(3) of the Law is one of the Board's methods of accomplishing the Law's purpose.

Water quality standards consist of narrative statements that describe water quality requirements in general terms, and of numeric limits for specific physical, chemical or biological characteristics of water. These narrative statements and numeric limits describe water quality necessary to meet and maintain reasonable and beneficial uses such as swimming, public water supply and the propagation and growth of aquatic life. Standards include general, as well as specific, descriptions since not all requirements for water quality protection can be numerically defined. In those cases where numeric standards have not been formulated for scientific or practical reasons, the general standards establish broad requirements to protect and maintain beneficial uses of State waters. Standards are not static. They will change and be constantly adjusted to reflect changes in law, technology and information available to the Board and its staff.

Standards are used in the administration of several Board programs. One is the issuance of permits for the discharge of treated wastewater under requirements of both Federal and State law. Federal law (the Clean Water Act) mandates that certain minimum treatment levels be achieved by all dischargers. Before the Board issues a discharge permit, it must first determine if those minimum levels are sufficient to maintain water quality standards in the receiving stream. If not, the Agency formulates and enforces more-stringent permit requirements which will allow water quality standards to be met. The Board's 401 Certificate program also uses water quality standards. Under Section 401 of the Clean Water Act, if a Federal permit is needed by any project which will or may result in a discharge to State waters, the project must first receive certification from the appropriate State that the project will not violate water quality standards. The State Water Control Board is the 401 certifying agency in Virginia, and it judges whether or not water quality standards will be contravened by proposed projects in administering this certificate program.

Water quality standards are intended to protect the beneficial uses of State waters. Virginia's standards do not assign specific uses to all streams, although they do specifically designate and protect trout streams and public water supplies. The standards are intended to protect all State waters for recreational use and for the propagation and growth of a balanced population of fish and wildlife. By protecting these two uses, which usually require the most stringent standards and the highest degree of protection, other usually less restrictive uses like industrial water supply, irrigation and navigation are usually also protected. Should additional standards be needed to protect other uses as dictated by changing circumstances or improved knowledge, they can be formulated and adopted.

Background

From its beginning in 1946 until the mid 1960's, the State Water Control Board generally approached control of water quality problems on a case-by-case basis, frequently through the adoption of wastewater treatment requirements for individual watersheds. By the mid 1960's, however, the Board was beginning to recognize the need for a program of water quality control with a broader, more extensive base — one that would deal with actual in-stream water quality throughout the entire state.

The Federal "Water Quality Act of 1965" (PL-89-234), provided the incentive and framework for such a program by requiring the establishment of certain water quality standards on a local, state and national scale. States which did not, or could not, adopt standards would have such standards of water quality established by the Federal government. As a result of the Federal Act amendments, and under State law, the Board first developed and adopted water quality standards in 1966 through 1968. They were substantially amended in 1970.

The 1972 amendments to the Federal Water Pollution Control Act (PL-92-500), restated the concept of water quality standards, and set certain water quality goals such as the attainment, by July 1, 1983, of water quality which provides for protection of fish, shellfish, and wildlife and for recreation in and on the water. In 1973 Virginia's water quality standards were slightly amended to ensure compliance with these aims.

This Act further required that a state's water quality standards be reviewed at least once every three years and, as appropriate, modified or amended. Virginia has completed one review period through public hearings in 1976 and formal adoption of amendments in 1977. The present standards have received Federal (Environmental Protection Agency) approvals required by the Act.

Development and Adoption

In order for water quality standards to be realistic while at the same time serving the stated purpose of maintaining or improving water quality, there first must be established a relationship between the standard itself and the benefit to be derived from adoption and enforcement of the standard. This relationship is generally determined by making certain studies, or evaluating already completed studies that define or attempt to define which standards and limits are required to provide needed levels of protection for certain water uses. A decision is then made regarding what levels of protection are desired. Finally, the appropriate standards and limits are chosen in order to provide the desired level of protection.

There are many sources of information or studies useful in the development of standards, and from time to time studies are conducted as needed by the Board or by consultants under contract to the Board. A major source of information is the publication *Quality Criteria for Water* published by the United States Environmental Protection Agency in 1976, pursuant to the requirements of the 1972 amendments to the Federal Water Pollution Control Act.

Since standards are designed to protect specific uses, the need for new or amended standards often comes about as a result of an identified new use of a body of water. For example, the Commission of Game and Inland Fisheries may identify a stream which was previously not known to support trout, as a natural trout stream. In this case the standards may be modified to protect this particular use. Also, a locality might want to use a stream as a water supply, and if the stream was not already classified as a public water supply, new standards would have to be applied to protect this use.

Information from every segment of the population is helpful in the development of standards, and their adoption can have wide-ranging effects. Public participation at all levels of standards development is therefore important to the adoption and implementation of standards which reflect the desire of the general public. The Law requires opportunity for public participation in the adoption of standards. Accordingly a public hearing with adequate public notice is mandatory before any standard can be adopted, amended, or cancelled. Following public notice of the hearing, the public has an opportunity to study the proposed standard and determine its effects. At the public hearing any person who is either for or against the proposed Board action on the standard may state his interest in the matter and enter relevant evidence into the hearing record.

Recent amendments to State Law added another mandatory consideration relative to standards – that the Board must give ample consideration to social and economic costs and benefits which will result from any action on the standard, whether by adoption, modification or cancellation.

Following the public hearing the Board's staff examines the hearing record, makes recommendations, and submits both the record and the recommendations to the Board for its consideration and action. Board action on a standard becomes effective thirty (30) days after filing with the Registrar of Regulations who keeps all standards and regulations of State agencies on file.

Both Federal and State legislators recognized the need for periodic review of all standards, and now both Federal and State law require that standards be reviewed at least every three years for possible changes and that the Board hold sufficient public hearings for public input. The Board is required to modify or cancel these standards, or to adopt new ones, as needed.

Summary and Explanation of Contents

This booklet contains the following seven sections:

1. Standards with General State-wide Application (Pages 5-11)

   These standards apply to waters on a State-wide basis and include such things as the General Standard, dissolved oxygen and temperature standards for surface waters, and groundwater standards.

2. Standards with More Specific Application (Pages 12-14)

   These standards have a specific application; they include, for example standards for public water supplies.

3. Procedural Requirements (Pages 14-15)

   This section includes rules that are a part of the standards such as a rule specifying acceptable analytical procedures for water testing.

4. River Basin Section Tables (Pages 15-65)

   This section divides the State's nine river basins into sections and indicates what specific standards apply to these specific sections.

5. Key to Special Standards (Pages 67-75)

   This section contains the entire printing of special standards that were too long to include in the tables of Section 4.

6. Water Quality Criteria (Pages 76-78)

   This section includes information about levels of pollutants to protect surface water and groundwater quality; they are not standards.

7. River Basin Maps (Plates 1-13)

   Maps in this part of the booklet delineate the river basin sections described in Section 4.

Additional more specific information can be found in the individual parts of the booklet.

In order to find applicable standards for a surface stream, first one must determine what River Basin Section the stream is in. This may be determined directly from the River Basin Section Tables or it may be necessary to determine the section by using the maps in Section 7.

The River Basin Section Tables indicate each section's Classification (Roman numeral I through VI). Paragraph 1.04 contains the standards that apply to the particular class and paragraphs 1.05 - 1.07 indicate other standards. The River Basin Section Tables also indicate whether any Special Standards apply to the stream. The entire special standard is printed in the special standards column if short; otherwise, a letter in the Special Standards Column refers the reader to the Special Standard which can be found in the Key to Special Standards Section, Section 5, beginning on page 67.

To determine applicable groundwater standards for an area, one can determine which physiographic province the area is in by checking Figure 1 on page 11, then by referring to the standards in Paragraph 1.09 on pages 9-10 that apply to that physiographic province.

In the sections that follow, all standards are shown in boldface type both in text and in tables. The text in lightface type preceding such standards is generally specific explanatory information relating to the standards that follow.

1. STANDARDS WITH GENERAL, STATEWIDE APPLICATION

General Standard

Because numeric limits cannot reasonably be developed for every possible chemical, physical or biological parameter, the standards include the following General Standard to protect water quality. This narrative statement, although written in general terms, is nonetheless a water quality requirement. For example, the Board may use the General Standard as a basis in establishing effluent limits for waste discharges that are necessary to insure protection of aquatic life even though there may be no specific numeric standard applicable in the receiving stream.

Part A of the General Standard sets the tone and requirement for all standards which follow. The language of Part A of the General Standard, although adopted by the Board as a State standard, finds its authority in the State Water Control Law, Section 62.1-44.2.

1.01 General Standard

A. All State waters shall be maintained at such quality as will permit all reasonable, beneficial uses and will support the propagation and growth of all aquatic life, including game fish, which might reasonably be expected to inhabit them.

B. All State waters shall be free from substances attributable to sewage, industrial waste, or other waste in concentrations, amounts, or combinations which contravene established standards or interfere directly or indirectly with reasonable, beneficial uses of such water or which are inimical or harmful to human, animal, plant, or aquatic life. Specific substances to be controlled include, but are not limited to: floating debris, oil, scum, and other floating materials; toxic substances, substances that produce color, tastes, turbidity, odors, or settle to form sludge deposits, and substances which nourish undesirable or nuisance aquatic plant life. Effluents which tend to raise the temperature of the receiving water will also be controlled.

C. Zones for mixing wastes with receiving waters shall be determined on a case-by-case basis; shall be kept as small as practical; shall not be used for, or considered as, a substitute for minimum treatment technology required by the Federal Water Pollution Control Act and other applicable State and Federal laws; and shall be implemented, to the greatest extent practicable, in accordance with the provisions of subsections A and B hereof. Mixing within these zones shall be as quick as practical and may require the installation and use of devices which insure that waste is mixed with the allocated receiving waters in the smallest practical area. The need for such devices will be determined on a case-by-case basis. The boundaries of these zones of admixture shall also be such as to provide a suitable passageway for fish and other aquatic organisms. In an area where more than one discharge occurs and several mixing zones are close together, these mixing zones shall be so situated that this passageway is continuous.

Anti-degradation

Setting numeric limits for pollutants by establishing water quality standards provides a minimum quality to which all high quality waters can theoretically be lowered unless additional controls are provided. The antidegradation policy prevents such wholesale lowering of all State waters to this "least common denominator of quality" by providing that waters with existing quality higher than the standards will be maintained at that high quality. The policy, however, does give the Board some flexibility in its administration of the standards. The policy is a direct quote from the State Water Control Law, Section 62.1-44.4, and, as such, is not subject to change by the State Water Control Board.

State law provides that any discharger must be required to utilize the necessary degree of waste treatment to maintain high water quality where physically and economically feasible. Present and anticipated use of such waters will be preserved and protected.

1.02 Anti-degradation Policy as contained in Section 62.1-44.4 of the State Water Control Law:

Waters whose existing quality is better than the established standards as of the date on which such standards become effective will be maintained at high quality; provided that the Board has the power to authorize any project or development, which would constitute a new or an increased discharge of effluent to

high quality water, when it has been affirmatively demonstrated that a change is justifiable to provide necessary economic or social development; and provided, further, that the necessary degree of waste treatment to maintain high water quality will be required where physically and economically feasible. Present and anticipated use of such waters will be preserved and protected.

Guidelines for Use in Implementing the Anti-degradation Policy

Existing instream beneficial water uses will be maintained and protected, and actions that would interfere with or become injurious to existing uses should not be undertaken.

In considering if a possible change is justifiable to provide necessary economic or social development, the Board will convene a public hearing so that interested persons will have an opportunity to present information.

Upon a finding that such change is justifiable, the change, nevertheless, must not result in violation of those water quality characteristics necessary to attain the national water quality goal of protection and propagation of fish, shellfish, and wildlife, and recreation in and on the water. Further, if a change is considered justifiable, it must not result in any significant loss of marketability of fish, shellfish or other marine resources.

Any determinations concerning thermal discharge limitations under Section 316(a) of PL 92-500 will be considered to be in compliance with the anti-degradation policy.

Standards Application; Stream Flow

Ideally stream standards should be maintained at all times. It is, however, generally accepted that to require standards maintenance at all times is unreasonable, and a specific low flow level has been chosen below which standards do not have to be met. This flow, as stated below, is the 7-day, 10-year low flow — or the lowest flow which, on a statistical basis, would occur for a seven consecutive day period once every 10 years.

1.03 Stream Standards will apply whenever flows are equal to, or greater than, the minimum mean 7-consecutive day drought flow with a 10-year return frequency.

Dissolved Oxygen, pH and Temperature Standards

Paragraphs 1.04 through 1.08 contain standards for dissolved oxygen, pH, and temperature.

The presence of dissolved oxygen (DO) in water is essential for aquatic life, and the type of aquatic community is dependent to a large extent on the concentration of dissolved oxygen present. Dissolved oxygen standards are established to insure the growth and propagation of aquatic ecosystems.

Stream pH is also an important factor in aquatic systems. Biological productivity, stream diversity, metal solubility, and toxicity of certain chemicals, as well as important chemical and biological activity, are strongly related to pH. The pH range of 6-8.5 generally provides adequate protection for aquatic life and for recreational use of streams. Some stream pH's however, fall outside this range due to natural conditions. When identified, these streams are assigned a pH standard that more properly reflects natural conditions. (The special standards for pH are contained in the Special Standards Column in the River Basin Section).

The existence and composition of an aquatic community also depends greatly on the temperature characteristics of a body of water. Thus temperature limits are included in water quality standards to protect and maintain a balanced, healthy aquatic community.

An excessive increase in temperature can be harmful by interfering with fish spawning cycles, causing changes in growth and respiration, and causing shifts in the population of an ecosystem as more heat-tolerant species replace heat sensitive ones. Heat-stressed organisms can exhibit decreased resistance to toxic pollutants, and excessive heat can even be lethal. Heat-related winter fish kills can occur when a heated discharge is suddenly stopped. Fish that

have been attracted to the thermal plume are suddenly exposed to the cold ambient temperature and, if the drop is great enough, it can be fatal.

Virginia's standards contain two approaches to temperature. In the first approach, maximum temperatures limits are established for the first six classes of water, specified in Paragraph 1.04 below, which are based on certain geographical areas and specified uses. (For example in Class IV waters – mountain streams – the maximum temperature is 31°C (88°F). The next two paragraphs (1.05 and 1.06) contain temperature standards, applicable to these six classes, for the maximum rise above the natural temperatures and for the maximum hourly temperature change. Although certainly simple to set and enforce, having a set of temperature standards that applies to a broad class of waters (For example to an entire system as complex as any estuary) is not ideal. Such an approach, by itself, cannot guarantee that the aquatic community at any given location is sufficiently protected. On the other hand, because one set of numbers applies to such broad areas and so must be conservative, the requirements can be unnecessarily restrictive in some areas. A second approach, establishing limits on a case-by-case basis, lessens these difficulties.

In this site-specific approach, temperature limits are tailored to a specific location; they are designed to protect the aquatic community actually present by taking into account the hydrologic, geologic and climatic conditions peculiar to the site. Thus they should provide sufficient protection without being unnecessarily restrictive.

To formulate temperature limits for an area, a set of guidelines – or criteria – is needed, and in 1977 the Board, recognizing the value of site-specific temperature standards, adopted the criteria found in paragraph 1.08 to use in setting future temperature limits. The specific limits are developed for one or more important and sensitive species at the site, thus assuring that the entire aquatic community can be protected.

Since developing site-specific temperature standards is complicated and time consuming, the Board has indicated that they should be developed primarily for waters receiving new thermal discharges of one million gallons per day or more. (Unless specifically indicated later in this booklet within the River Basin Section's Special Standards Column [Section 4], site specific standards have not been adopted for a site and the appropriate temperature standards of Paragraphs 1.04, 1.05, 1.06 and 1.07, apply.)

Classification of Waters Within the State: Dissolved Oxygen, pH, Maximum Temperature Standards

All State surface waters are assigned one of the following seven Classes based on geographic location, or type of trout water. The limits set forth in Paragraph 1.04 for the appropriate class are the enforceable water quality standards for the waters unless an exception is made by a special standard. (A listing of the Classes assigned to particular areas can be found in Section 4 – River Basin Section Tables. That Section also indicates in the Special Standards Column if there are any special standards in addition to – or differing from – limits listed below.)

1.04 Standards for DO, pH, and Maximum Temperature

CLASS	DESCRIPTION OF WATERS	DISSOLVED OXYGEN mg/l		pH	MAX. TEMP. °C
		Minimum	Daily average		
I	Open Ocean	5.0	––	6.0-8.5	––
II	Estuarine (Tidal Water-Coastal Zone to Fall Line)	4.0	5.0	6.0-8.5	––
III	Free Flowing Streams (Coastal Zone and Piedmont Zone)	4.0	5.0	6.0-8.5	32
IV	Mountainous Zone	4.0	5.0	6.0-8.5	31
V	Put and Take Lake Trout Waters	5.0	6.0	6.0-8.5	21
VI	Natural Trout Waters	6.0	7.0	6.0-8.5	20
VII	Swamp Water	*	*	*	**

*This classification recognizes that the natural quality of swamp water may fall outside of the ranges for D.O. and pH set forth above as water quality standards; therefore, on a case-by-case basis, standards for specific swamp waters can be developed that reflect what natural quality is.

**Maximum temperature will be the same as that for Classes I through VI waters as appropriate.

See Section 3.04, page 15 for requirements for analytical procedures.

1.05 Rise above natural temperature

Any rise above natural temperature allowed by the Board shall be determined on a case-by-case basis and should not exceed 3°C except in the case of Class VI waters (natural trout waters) where it shall not exceed 1°C. Natural temperature is defined as that temperature of a body of water (measured as the arithmetic average over one hour) due solely to natural conditions without the influence of any point-source discharge.

1.06 Maximum hourly temperature change

The maximum hourly temperature change shall not exceed 2°C, except in the case of Class VI waters (Natural trout waters) where it shall not exceed 0.5°C. This standard (limit) is to apply beyond the boundaries of mixing zones and does not apply to temperature changes caused by natural conditions.

1.07 Thermal discharges into lakes and impoundments

In lakes and impoundments receiving thermal discharges, the average temperature of the epilimnion, [surface water layer], in those areas where important organisms are most likely to be affected, shall not be raised more than 3°C above that which existed before the addition of heat of artificial origin. (The permissible increase shall be determined on a case-by-case basis, and in some instances may be less than 3°C). The increase is to be based on the monthly average of the maximum daily temperature. The temperature of releases from these lakes and impoundments shall be consistent with standards established for the receiving waters. Unless a special study shows that a discharge of heated effluent into the hypolimnion (or pumping water from the hypolimnion for discharging back into the same water body) will not produce adverse effects, such practice shall not be approved. Maximum temperatures consistent with the standards established for water immediately above and below the lake or impoundment will be established for these waters.

Site specific temperature standards

The temperature limits set forth in Paragraph 1.04 may be superseded in certain locations by temperature standards developed specifically for that area. (The existence of site specific standards is indicated in the Special Standards Column, otherwise the appropriate temperature limits in paragraphs 1.04, 1.05, 1.06 and 1.07 will apply.) In developing specific temperature standards, the following criteria will be used:

1.08 Criteria for Developing Site Specific Temperature Standards

The temperature standards shall be based on:

1. **One limit which consists of a maximum weekly average temperature that:**

   a. **In the warmer months is determined by adding to the physiological optimum temperature (usually for growth) a factor calculated as one-third of the difference between the ultimate upper incipient lethal temperature and the optimum temperature for the most sensitive important species (and appropriate life stage) that normally is found at that location and time.**

   b. **In the cooler months is an elevated temperature that would still ensure that important species would survive if the temperature suddenly dropped to the normal ambient temperature, or**

   c. **during reproduction seasons meets specific site requirements for successful migration, spawning, egg incubation, fry rearing, and other reproductive functions of important species; or**

   d. **at a specific site is found necessary to preserve normal species diversity or prevent undesirable growths of nuisance organisms.**

2. **A second limit which is the time-dependent maximum temperature for short exposures.**

Baseline thermal conditions should be measured at a site where there is no unnatural thermal addition from any source, which is in reasonable proximity to the thermal discharge (5 miles), and which has similar hydrography to that of the receiving waters at the discharge.

Standards development should be in accordance with *Water Quality Criteria 1972: A Report of the Committee on Water Quality Criteria* and *Quality Criteria for Water*, U. S. Environmental Protection Agency.

Groundwater Standards

With the 1977 amendments to Water Quality Standards, Virginia became one of the first states to adopt standards and criteria to protect and preserve the quality of its groundwater resources.

About one out of every four Virginians depends on groundwaters for drinking water. Also in times of dry weather and low stream flow, many streams are supplied totally by groundwater. Therefore, the Board considers it important to insure that groundwater quality is protected. The standards and criteria adopted by the Board in 1977 consist of limits designed to protect and conserve the natural quality of groundwater and to provide guidance for preventing groundwater pollution (See Paragraph 6.02 for groundwater criteria).

Although differing hydrogeologic conditions can cause state-wide variations in natural groundwater quality, it was found that within certain physiographic provinces of the State relatively uniform and consistent groundwater conditions exist. For each of these areas, chemical and physical analyses of groundwater samples on file at the State Water Control Board were evaluated, and concentrations that were representative of about 90% - 95% of the samples were selected as the standard for each constituent. The numbers selected are therefore representative of the prevalent natural condition of that constituent in any particular province.

The groundwater standards also include an antidegradation policy which is intended to ensure that naturally occurring groundwater quality is not degraded. This policy does provide that in limited cases some changes in natural quality could be allowed. The groundwater standards represent groundwater quality that should be preserved or attained. Natural variations in quality occur because of local hydrogeologic conditions and thus exceptions to statewide standards do occur occasionally throughout the State. Therefore refinement to or variance from groundwater standards can be made where specific data confirm a natural variation.

1.09 Groundwater Standards

Groundwater quality standards will apply statewide and will apply to all groundwater occurring at and below the uppermost seasonal limits of the water table. In order to prevent the entry of pollutants into groundwater occurring in any aquifer, a soil zone or alternate protective measure or device sufficient to preserve and protect present and anticipated uses of groundwater shall be maintained at all times. Zones for mixing wastes with groundwater may be allowed, upon request, but shall be determined on a case-by-case basis and shall be kept as small as possible.

It is recognized that natural groundwater quality varies statewide. Four Physiographic provinces have been determined for application of standards, namely the Coastal Plain, Piedmont and Blue Ridge, Valley and Ridge, and Cumberland Plateau. (See Figure 1, page 11.)

Antidegradation policy for groundwater

If the concentration of any constituent in groundwater is less than the limit set forth by groundwater standards, the natural quality for the constituent shall be maintained; natural quality shall also be maintained for all constituents, including temperature, not set forth in groundwater standards. If the concentration of any constituent in groundwater exceeds the standard for that constituent, no addition of that constituent to the naturally occurring concentration shall be made. Variance to this policy will not be made unless it has been affirmatively demonstrated that a change is justifiable to provide necessary economic or social development, that the necessary degree of waste treatment cannot be economically or socially justified, and that the present and anticipated uses of such water will be preserved and protected.

GROUNDWATER STANDARDS BY PHYSIOGRAPHIC PROVINCE				
CONSTITUENT	CONCENTRATION			
	Coastal Plain	Piedmont & Blue Ridge	Valley & Ridge	Cumberland Plateau
pH	6.5-9	5.5-8.5	6-9	5-8.5
Ammonia Nitrogen	0.025 mg/l	0.025 mg/l	0.025 mg/l	0.025 mg/l
Nitrite Nitrogen	0.025 mg/l	0.025 mg/l	0.025 mg/l	0.025 mg/l
Nitrate Nitrogen	5 mg/l	5 mg/l	5 mg/l	0.5 mg/l

GROUNDWATER STANDARDS—STATEWIDE

2. STANDARDS WITH MORE SPECIFIC APPLICATION

Bacterial Standards

Virginia's water quality standards include two fecal coliform bacteria standards – one for shellfish waters and one for all other waters. These "indicator organisms," while not necessarily harmful in themselves, are found in the intestinal tracts of warmblooded animals, including humans, and therefore can be indicative of fecal contamination and the possible presence of pathogenic organisms.

SHELLFISH WATERS

For waters containing leased private or public shellfish beds and waters capable of propagating shellfish, the following standard is established for fecal coliform bacteria. The limit is consistent with requirements of the State Health Department's Bureau of Shellfish Sanitation and the U. S. Food and Drug Administration – the State and Federal agencies, respectively, charged with administering shellfish sanitation programs.

2.01 Fecal Coliform Bacteria – Shellfish Waters

In all open ocean or estuarine waters capable of propagating shellfish or in specific areas where public or leased private shellfish beds are present, and including those waters on which condemnation or restriction classifications are established by the State Department of Health, the following standard for fecal coliform bacteria will apply:

The median fecal coliform value for a sampling station shall not exceed an MPN of 14 per 100 ml of sample and not more than 10% of samples shall exceed 43 for a 5 tube, 3 dilution test or 49 for a 3 tube, 3 dilution test.

OTHER WATERS

Waters other than shellfish waters are assigned the following coliform bacteria standard which is designed to protect waters for all types of recreation. Before 1977, Virginia's standards contained two such bacteria standards – one of which was intended to protect waters known or thought to be used for "primary contact recreation," e.g. swimming; and a less stringent standard which was intended to protect waters for "secondary contact recreation," e.g. – boating or fishing. In its 1977 amendments to Virginia's Water Quality Standards, the Board adopted the more stringent bacteria standard for primary contact recreation to apply to all surface waters of the State. This action was taken as part of Virginia's commitment to attain by 1983, the national goal of water quality suitable for all types of recreation.

2.02 Fecal Coliform Bacteria – Other Waters

In all surface waters, except those where leased private or public shellfish beds are present, the fecal coliform bacteria shall not exceed a log mean* of 200 fecal coliform bacteria per 100 ml of water with not more than 10 percent of the total samples during any 30-day period exceeding 400 per 100 ml. Evaluation should be determined by either the multiple-tube fermentation for marine water or the membrane filter method for fresh water and should be based upon not less than ten samples taken over not more than a 30-day period.

Water Quality Standards for Surface Public Water Supplies

Although protection of public health and regulation of public drinking water supplies fall primarily within the purview of the State Health Department, the State Water Control Board does have the responsibility to protect the quality of water in streams used as a raw source for drinking water supplies. To this end the Board has adopted

*geometric mean

standards for application to specific drinking water sources. Because some pollutants are not significantly removed by conventional water treatment systems, and to insure protection of the water supply, the stream standards for those pollutants are the same as the limits required for protection of public health in the finished drinking water.

In order to emphasize the need to protect a specific body of water for use as a source for a public water supply, each such area has been designated as a separate section in the River Basin Section Tables of Section 4. The section usually begins at the intake point and usually extends 5 miles upstream. (If a watershed is not significantly larger than 5 miles above the intake the water supply section may include the entire upstream watershed to its headwaters.) This designation as a separate section is primarily an administrative method of pointing out a water supply source and emphasizing the need to protect the stream.

The public water supply standards usually apply only at the raw water intake point. Of course, the upstream water quality must be such that specific limits will be met at the intake point. In cases where the specific numeric limits are adopted to apply for some additional upstream distance to provide further protection for the water source, the section description in the River Basin Section Tables will indicate this fact and point out the additional distance. Lacking such special notation, the public water supply standards apply only at the intake point.

Public Water Supply Standards and Protection of Aquatic Life

The Public Water Supply Standards are designed to protect water quality for human consumption. These limits, however, in some cases may not be sufficient to protect aquatic life. Many aquatic organisms are more sensitive to certain pollutants than humans and would, of course, be under constant exposure to any such pollutant in their environment. Therefore, when the Board considers classifying a body of water as a public water supply, an evaluation of the aquatic community in that area is made to determine if water quality concentration limits must be more stringent for any particular parameter to protect the aquatic community. (The concentrations for those pollutants that are marked with an asterisk (*) are the ones most likely to be too high to protect aquatic life, although adequate to provide protection for human consumption.) This procedure will ensure that any specific numeric limits adopted as enforceable standards for a public water supply will be stringent enough to protect aquatic life.

2.03 Surface Water Standards for Surface Public Water Supplies

In addition to other standards established for the protection of public or municipal water supplies, the following standards will apply at the water intake and, if determined to be appropriate, for a distance upstream, and in the case of the streams influenced by tidal action, downstream also. This distance from the intake is to be determined on a case-by-case basis by the Board considering upstream wastewater volume, receiving stream volume and other appropriate physical, chemical and biological factors. The standards will apply to both the water supply stream and its tributaries within the designated distance. (In case of existing water supplies, the standards will apply at the intake point until further change is made.)

CONSTITUENT	CONCENTRATION (MG/L)
Arsenic	0.05
Barium	1.0
Cadmium*	0.01
Chloride	250
Chromium (Total)	0.05
Copper*	1.0
Foaming agents (measured as methylene blue active substances)	0.5
Iron (soluble)	0.3
Lead	0.05
Manganese (soluble)	0.05
Mercury*	0.002
Nitrate (as N)	10
Phenols	0.001
Selenium*	0.01
Silver*	0.05
Sulfate	250
Total dissolved solids	500
Zinc*	5.0

CONSTITUENT	CONCENTRATION (MG/L)
Chlorinated Hydrocarbon Insecticides:	
Endrin*	0.0002
Lindane*	0.004
Methoxychlor*	0.1
Toxaphene*	0.005
Chlorophenoxy Herbicides:	
2, 4-D	0.1
2, 4, 5-TP (Silvex)	0.01
Radioactivity:	**picocurie/liter**
Combined radium - 226 and radium - 228 -	5
Gross alpha particle activity (including radium - 226 but excluding radon and uranium)	15

*The numeric standards for the chemicals listed in Paragraph 2.03 above are designed to protect public water supplies for human consumption. The limits established for those chemicals marked with an asterisk (*) may not protect aquatic life. Therefore when a request to classify a stream as a public water supply is received, it will be determined if more stringent limits are needed for those chemicals in order to insure protection of aquatic life.

3. PROCEDURAL REQUIREMENTS

This section contains statements and requirements that are a part of the standards adopted by the Board; these requirements are enforceable.

3.01 Variance in Standards

The above standards notwithstanding, as a result of natural conditions, water quality may from time to time vary from established limits.

3.02 Modification, Amendment and Cancellation of Standards

In accordance with the authority granted under Section 62.1-44.15(3)(b) of the State Water Control Law, Chapter 3.1, Title 62.1, Code of Virginia (1950), as amended, the Board reserves the right at any time to modify, amend, or cancel any of the rules, policies, or standards set forth herein; such modification, amendment, or cancellation shall be consistent with requirements of Section 303 of the Federal Water Pollution Control Act, as amended and regulations promulgated thereunder.

3.03 Shellfish Buffer Zones — Public Hearing

Discharges of treated wastes or proposals to otherwise alter the biological, chemical or physical properties of State waters, submitted to the Board for approval, while not contravening established standards for shellfish waters may prevent the direct marketing of shellfish as a result of judgment factors employed by the State Department of Health. When the possibility of such condemnation arises as the result of such proposals, the Board will convene a public hearing to determine the socio-economic effect of the proposal before reaching a decision, unless the appropriate State agencies, (the Bureau of Shellfish Sanitation and/or the Marine Resources Commission) certify that the project would have no effect on the shellfish industry now and in the foreseeable future.

3.04 Analytical Procedures

Analytical testing should be done in accordance with accepted procedures in the appropriate edition of *Standard Methods for the Examination of Water and Wastewater* or other Board/EPA recognized and approved methods.

3.05 Tidal Water Sampling

Samples for determining compliance with standards established for estuarine or open ocean waters will be collected at slack before flood tide or slack before ebb tide.

4. RIVER BASIN SECTION TABLES

A. Section Number and Description Columns

The tables that follow divide the State's surface waters into nine river basins, some with subbasins: Potomac River Basin (Potomac and Shenandoah Subbasins), James River Basin, Rappahannock River Basin, Roanoke River Basin (Roanoke and Yadkin Subbasins), Chowan and Dismal Swamp Basin (Chowan and Albemarle Sound Subbasins), Tennessee and Big Sandy Basins (Big Sandy, Clinch and Holston Subbasins), Chesapeake Bay, Atlantic Ocean and Small Coastal Basins, York River Basin and New River Basin. (See Figure 2. page 17.)

Each basin is further divided into sections. Each section is assigned a Class, represented by Roman numerals I through VII, based on its geographic location or, in the case of trout waters, on its use. Descriptions of these Classes are found in paragraph 1.04, page 7.

B. Classification Column: DO, pH, Temperature Standards

Paragraph 1.04. on page 7 lists Classes I through VII and the water quality standards for dissolved oxygen (DO), pH, and maximum temperature, that apply to each class. (For example, as shown on page 27, Section 1 of the James River Basin is indicated as being Class II waters (estuarine). By referring to paragraph 1.04 the DO, pH, and maximum temperature for this Section can be found along the line following Class II.

C. Special Standards Column

1. Bacteria Standards

   All surface waters have a standard for fecal coliform bacteria. The bacteria standard for shellfish waters is set forth in Paragraph 2.01; the standard applying to all other surface waters is found in Paragraph 2.02. The letter *a* in the Special Standards Column next to a River Basin Section indicates that there are shellfish waters somewhere within that section and the bacteria standard for shellfish waters applies to those shellfish waters. (It should be noted that even though the column contains the letter *a* the entire section may not be shellfish waters.)

   The bacteria standard in paragraph 2.02 applies to all other surface waters.

2. Natural Variation

   In some cases natural water quality does not fall within the limits set by the standards. (For example streams in some areas of the State can naturally exceed the usual pH range of 6 to 8.5.) In these instances the Board may have set a more appropriate standard that reflects natural quality, and this "special limit" is shown in the Special Standards Column.

3. Additional Requirements

In other cases the "basic" water quality parameters of DO, pH, temperature, and bacteria have not been sufficient to protect water quality in certain areas, and effluent limits or treatment requirements have been established for these areas. This fact is also indicated in the Special Standards Column. If the standard was too long to print in its entirety, the column contains only a lower case letter and the standard itself will be found in the Key to Special Standards Section Paragraph 5.01, under this letter.

4. Other Special Standards or Designations

a. Public Water Supplies

The Special Standards Column also indicates sections that are public water supplies with a "PWS" (This designation indicates that additional standards are applicable. (See Section 2.03, page 13.)

b. "Scenic Rivers"

The Special Standards Column also indicates if a section contains a stream that has been designated a scenic river by the General Assembly with an SR- followed by a number. The appropriate waterway can be found listed in the Key to Special Standards Section under Scenic Rivers, Paragraph 5.02, page 74.

5. KEY TO SPECIAL STANDARDS AND INFORMATIONAL DESIGNATIONS

5.01 Specific Standards and Requirements

a. Shellfish Waters

In all open ocean or estuarine waters capable of propagating shellfish or in specific areas where public or leased private shellfish beds are present, including those waters on which condemnation or restriction classifications are established by the State Department of Health, the following standard for fecal coliform bacteria will apply:

The median fecal coliform value for a sampling station shall not exceed an MPN of 14 per 100 ml of sample and not more than 10% of samples shall exceed 43 for a 5 tube, 3 dilution test or 49 for a 3 tube, 3 dilution test.

The shellfish area is not to be so contaminated by radionuclides, pesticides, herbicides, or fecal material that the consumption of shellfish might be hazardous.

b. Potomac Embayment Standards

The standards of quality, based on a one-month average, for all sewage treatment plant effluents discharging into Potomac River embayments in Virginia from Jones Point (Hunting Creek) to the Route 301 Bridge, and for expansions of existing plants discharging into the non-tidal tributaries of these embayments, are:

			NOTES
1.	Biochemical oxygen demand	Not greater than 3 ppm	A, B
2.	Unoxidized nitrogen	Not greater than 1.0 ppm during the periods April 1 - Oct. 31	B, C
3.	Total phosphorus	Not greater than 0.2 ppm	D
4.	Total nitrogen (when technology is available)	Not greater than 1 ppm	E

Background notes

A. **This BOD_5 standard is a factor of three less stringent than that being presently produced at the Lake Tahoe plant which is approximately 1 ppm of BOD_5.**

B. **A BOD_5 of 3 ppm and 1 ppm of unoxidized nitrogen will result in a UOD of approximately 10 ppm.**

C. **To achieve this level of unoxidized nitrogen, nitrification can be accomplished by limiting the BOD_5 load on aeration units to 25 pounds per 1000 cubic feet or less and designing the aeration units to maximize the "plug-flow" principle.**

D. **This phosphorus standard is a factor of two less stringent than that being presently produced at the Lake Tahoe plant which is 0.1 ppm or less of P.**

E. **For the time being the requirement for total nitrogen removal is waived. However, all plants will have to have facilities to meet this standard as soon as practical after a technically feasible process with year-round reliability is developed and available.**

These standards were adopted as the result of a study by the Chesapeake Technical Support Laboratory of the Federal Water Quality Administration (now EPA) which recommended certain maximum effluent concentration limits for ultimate oxygen demand, phosphorus and nitrogen to maintain and improve water quality, and a public hearing held on March 30, 1971. The standards shown above were adopted at the June 14-15, 1971, Board meeting (Minute 42) to apply from Jones Point to Marlboro Point (Aquia Creek). At its June 10-11, 1974, meeting (Minute 4) following a March 28, 1974 hearing, the Board extended the standards to the Route 301 Bridge.

c. Williams and Upper Machodoc Creeks

The following criteria will be applied to proposals for sewage treatment facilities which will discharge effluent to Williams and Upper Machodoc Creek, King George County:

1. **If raw sewage stabilization ponds are proposed, they shall be followed by a 15-day holding pond and chlorination facilities in duplicate;**

2. **If "conventional" sewage treatment facilities are proposed, they shall effect at least 85% removal of BOD and shall be followed by a 15-day holding pond and chlorination facilities in duplicate;**

3. **Chlorination facilities are to be operated continuously during the entire year and chlorine residual of at least 2.0 ppm shall be maintined at all times;**

4. **In sewerage systems where pumping stations are found to be necessary, they shall be designed to prevent the discharge of raw sewage to State waters;**

5. **If, in the opinion of the staff, following consultation with the State Department of Health it is determined that more satisfactory water quality can thereby be maintained in the receiving stream, the holding pond shall be operated to provide for controlled flow discharge.**

The purpose of these criteria was to establish a Board regulation with respect to the discharge of treated effluents to the two watersheds, because of the likelihood of increased development in the area and the need to protect water quality and beneficial water uses, especially shellfish growing. Adoption of the criteria at the May 17-18, 1966, Board meeting (Minute 59) followed a public hearing on May 5, 1965. They were slightly amended in April 1970.

d. Aquia Creek

No proposal resulting in the discharge of treated wastes to Aquia Creek will be approved unless the following is provided.

1. **At least 100 days' storage to allow complete elimination of discharges during the low-flow summer months or**

2. **Other treatment, based on sound engineering concepts (preferably with experimental data to show their feasibility), be provided for nutrient removal prior to discharge.**

The above requirements were initially adopted by the Board at its meeting of June 30-July 1, 1964 (Minute 71) to protect the recreational uses of Aquia Creek. They were based on information received at a public hearing before the Board at its meeting on June 30 and July 1, 1964.

e. Lakes with Thermal Discharges

The following temperature standard will apply to lakes and impoundments receiving thermal discharges.

> **In lakes and impoundments receiving thermal discharges, the average temperature of the epilimnion, in those areas where important organisms are most likely to be affected, shall not be raised more than 3°C above that which existed before the addition of heat of artificial origin. (The permissible increase shall be determined on a case-by-case basis and in some instances may be less than 3°C) The increase is to be based on the monthly average of the maximum daily temperature. The temperature of releases from these lakes and impoundments shall be consistent with standards established for the receiving waters. Unless a special study shows that a discharge of heated effluent into the hypolimnion (or pumping water from the hypolimnion for discharging back into the same water body) will not produce adverse effects, such practice shall not be approved. Maximum temperatures consistent with the standards established for water immediately above and below the lake or impoundment will be established for these waters.**

This thermal standard was incorporated into water quality standards with the 1970 amendments and was subsequently amended in March 1977.

f. **Potomac Enforcement Conference - Recommendation 1**

On May 8, 1969, conferees to a Potomac Enforcement Conference, covering the 26-mile stretch from Little Falls to Hallowing Point just below Gunston Cove, made 15 recommendations. The following requirments of Recommendation 1 from that conference pertain to Virginia treatment facilities:

Based on the existing points of discharge, waste treatment facilities now discharging to the Potomac River between river mile 106 and river mile 91 (the 15 mile stretch of the river from Chain Bridge downstream to the vicinity of Hog Island) shall be improved to achieve removal of BOD_5, total phosphorus, and total nitrogen so as to limit loadings as follows:

FACILITY	LBS/DAY		
	BOD_5	TOTAL P	TOTAL N
Arlington	1,300	60	650
Alexandria	1,300	60	630
Fairfax Westgate	900	40	445

Additional loading and additional points of discharge will be acceptable only if the resultant water quality will be equal to, or better than, that which results from adherance to the above load limits at the existing points of discharge.

The following treatment plants shall provide 96% BOD_5 removal, 96% phosphorus removal, and 85% total nitrogen removal, so long as they discharge their effluents to tributaries or embayments of the Potomac River: Fairfax County Doque Creek, Little Hunting Creek, and Accotink-Pohick (Lower Potomac) treatment plants; and Fort Belvoir.

NOTE: In accordance with Board action in Minute 13 from its meeting on September 20-21, 1971, discharges which lie within boundaries of the Potomac Enforcement Conference (Little Falls to Hallowing Point) and of the Potomac Embayment Standards (Hunting Creek- Jones Point to the Route 301 Bridge) must comply with the more restrictive provisions of the two.

Prior to the 1972 Amendments to the Federal Water Pollution Control Act, Federal water pollution control agencies convened a conference of all parties involved in order to take enforcement action relative to water pollution abatement. Such an "Enforcement Conference" was held concerning the Potomac River in the Washington, D.C., metropolitan area in the late 1950's and was reconvened in 1968. The area covered by this conference was a 26-mile stretch of the River, from Little Falls to Hallowing Point. Recommendation 1 of the 15 recommendations made by the conferees on May 8, 1969, set allowable daily loads or percent removals for BOD, nitrogen and phosphorus for discharges into the river. The limits were based on a study done by FWPCA's Annapolis laboratory, which determined assimilation capacities of the river in the conference area and the downstream estuary.

g. **Occoquan Watershed Policy**

At its meeting on July 26, 1971, (Minute 10) the Board adopted a comprehensive pollution abatement and water quality management policy for the Occoquan watershed. The policy set very stringent treatment and discharge requirements in order to improve and protect water quality, particularly since the waters are an important water supply for Northern Virginia areas. Following a public hearing on November 20, 1980, the Board, at its December 10-12, 1980, meeting, adopted as of February 1, 1981, revisions to this Policy (Minute 20). These revisions became effective March 4, 1981. Copies are available upon request from the State Water Control Board.

h. **Chlorides not to exceed 800 mg/l at any time.**

i. Powhatan Creek Watershed

The following, from Minute 20 of the proceedings of the Board at its meeting on January 16, 1969, will also apply to the Powhatan Creek Watershed in James City County:

1. **All proposals for treated waste discharges to the Powhatan Creek Watershed will in the future be approved only after:**

   a. **Engineering data have been submitted indicating the capability of the proposed treatment facilities to remove all phosphorus and nitrogen compounds.**

   b. **Owners with facilities existing at the time of this action will, in a period not to exceed 60 days, submit to the Board engineering reports and pollution abatement schedules indicating the maximum concentrations of phosphorus and nitrogen compounds which they can remove from waste waters prior to discharge. No schedule providing a time period exceeding three years will be approved. Modification or replacement of existing treatment facilities may be necessary.**

2. **It will entertain from owners in the area a proposal for development of:**

   a. **A central facility to treat all wastes at a point outside the Watershed, where phosphorus and nitrogen removal will probably not be necessary, or**

   b. **Treatment facilities inside the Watershed which include complete removal of all phosphorus and nitrogen compounds.**

3. **If the above plan is accompanied by a firm schedule leading to completion of sewage treatment facilities within a reasonable length of time, and it can be demonstrated that the financing for the facilities is available, the Board will consider allowing interim construction of sewage treatment facilities in the Powhatan Creek Watershed without the requirement of phosphorus and nitrogen compound removal.**

These requirements for the Powhatan Creek Watershed were developed to attempt to alleviate the secondary pollution problems due to algae growth developing in the tidal waters of Powhatan Creek which, the Board felt, would in all probability become more intensive with expected population growth and its attendant waste discharges. They were adopted following a public hearing on September 17, 1968.

j. **For the Lynnhaven River and Eastern Branch Elizabeth River Watersheds the following applies:**

   Objective for Nutrients - The cumulative total of nitrogen as N from all sources in the effluent shall not be greater than 0.5 mg/l at any time; phosphorus as P from all sources in the effluent shall not be greater than 1.0 mg/l at any time.

k. **For the Lynnhaven River and Eastern Branch Elizabeth River Watersheds the State Water Control Board has directed and/or ordered the following:**

1. **That all existing discharges in accordance with j above shall substantially remove the nutrients in their effluents on or before such time as central facilities (The Hampton Roads Sanitation District Commission Chesapeake-Elizabeth System) become available or connect to central facilities, (i.e. The Chesapeake-Elizabeth System).**

2. **That it will consider approving small discharges to this watershed to facilitate the elimination of potential public health hazards provided central facilities (Chesapeake-Elizabeth System) are not available, and**

3. **That it will not allow additional significant new discharges to this watershed, which do not provide for nutrient removal facilities in accordance with j above.**

In 1961 a water quality survey was made of the Lynnhaven watershed; - In 1964, a survey was undertaken on the Eastern Branch of the Elizabeth River resulting in a Board report entitled "An Evaluation of Water Quality

nutrient enrichment.

2. The watersheds have poor flushing characteristics.

3. Nutrients causing water quality problems should be removed from discharges into the watershed or the discharges themselves should be removed.

The wastewater treatment requirements of j and k above attempted to accomplish removal of nutrients from the streams.

l. **Nansemond River Watershed**

The following requirements, from Minute 1 of the proceedings of the Board at its meeting on July 20-21, 1965, were adopted to apply to the Nansemond River Watershed from the river's confluence with the James River upstream to the dam at Lake Meade in Suffolk:

2. **All known existing treated discharges containing bacteria shall be chlorinated sufficiently and continuously (100% of the time) to maintain a residual which will insure substantially complete removal of coliform organisms. This action is to be instituted immediately by all concerned owners.**

3. **All owners now discharging industrial wastes and sewage shall install facilities which will provide the maximum possible degree of biochemical oxygen demand (BOD) removal; in addition, the effluent from such facilities shall contain a minimum of 5 mg/l of dissolved oxygen (D.O.).**

4. **All owners in the area (City of Suffolk, County of Nansemond, industrial establishments and individuals) shall immediately take steps to collect and treat, in accordance with items 2 and 3 above, the wastes that are now being discharged untreated either directly or indirectly to the River and Shingle Creek and which now constitute a health hazard to the area.**

5. **The City of Suffolk, the County of Nansemond, and those private owners who are now discharging sewage and industrial wastes to these waters are to immediately initiate programs to formulate a plan, or alternative plans, for improving water quality in the River and Shingle Creek. Alternative plans may include conveying all wastes completely from out of this watershed for treatment and/or disposal. Only under exceptional circumstances will additional discharges of treated wastes into these waters be permitted.**

The Board established these requirements because, based on evidence presented at a public hearing on May 4-5, 1965, and the information presented by the staff in its technical report entitled "The Nansemond River Watershed - Water Quality Aspects", it determined that portions of the watershed were degraded to the point of the contravention of certain uses.

m. **The following effluent standards apply to the entire Chickahominy Watershed above Walker's Dam:**

	CONSTITUENT	CONCENTRATION
1.	**Bio-chemical Oxygen demand 5-day at 20^{o}**	**6.0 mg/l monthly average, with not more than 5% of individual samples to exceed 8.0 mg/l**
2.	**Settleable Solids**	**Not to exceed 0.1 ml/l**
3.	**Suspended Solids**	**5.0 mg/l monthly average, with not more than 5% of individual samples to exceed 7.5 mg/l**

	CONSTITUENT	CONCENTRATION
4.	**Ammonia Nitrogen**	**Not to exceed 2.0 mg/l as N**
5.	**Total Phosphorus**	**Not to exceed 0.1 mg/l monthly average for all discharges with the exception of Holly Farms Poultry Industries, Inc. which shall meet 0.3 mg/l monthly average and 0.5 mg/l daily maximum**
6.	**Other Physical and Chemical Constitutents**	**Other physical or chemical constituents not specifically mentioned will be covered by additional specifications as conditions determental to the stream arise. The specific mention of items 1 through 5 does not necessarily mean that the addition of other physical or chemical constituents will be condoned.**

Standards to protect the Chickahominy Watershed are long-standing. The Watershed is impounded by Walker's Dam, serves as a water supply source for the City of Newport News, is an excellent fishery and is in an area which is subject to growth pressure. To protect the watershed from water quality problems associated with these factors and to protect existing and intended water uses, in July 1966, the Board adopted standards of effluent quality for discharges into the watershed above Walker's Dam. The action was based on information obtained in a July 11-12, 1966, public hearing and the staff's technical report entitled "A Water Quality Study of the Chickahominy River". In 1970 amendments were proposed to update the effluent standards. They were considered in a November 18, 1970, public hearing and adopted in February 1971 in unanimous letter ballot 2144. Following a public hearing on March 17, 1981, the Board, by unanimous vote on letter ballot 4862 dated April 13, 1981, adopted revisions to this special standard. These revisions are incorporated in Items 1-6 above, and became effective December 12, 1981.

n. **The following, from Minute 38 of the proceedings of the Board at its meeting on March 30, 1955, will also apply:**

No sewage discharges, regardless of degree of treatment, should be allowed into the James River between Bosher and Williams Island Dams.

The Board's action was based upon the following items:

1. During periods of low stream flows, all flow in a portion of the James below Boshers Dam virtually stops due to the diversion of water behind the dam into a canal;

2. The City of Richmond's water supply is usually obtained from the James River at Williams Island (except during those low flow periods when the river's flow is diverted into the above-mentioned canal and the City's supply is taken only from the canal).

3. Recreational uses, including swimming and fishing, are well established in the area.

o. **The following from Minute 32 of the proceedings of the Board at its meeting on September 13, 1960, will also apply:**

The concentration and total amount of impurities in Tuckahoe Creek and its tributaries of sewage origin shall be limited to those amounts from sewage, industrial wastes, and other wastes which are now present in the stream from natural sources and from existing discharges in the watershed.

This "no net increase of material of sewage origin" policy for the Tuckahoe Creek watershed was developed to protect various uses of the creek, including its use as an auxiliary water source for the City of Richmond, in light of anticipated population growth in the Henrico, Goochland, and Hanover portions of the Watershed.

p. Radiation Standard

1. **Radium-226 not to exceed 3 pc/l.**
   Strontium-90 not to exceed 10 pc/l.

2. **In the known absence of strontium-90 and alpha-emitting radionuclides, gross beta activity not to exceed 1,000 pc/l.**

3. **If the gross beta activity is in excess of this amount, a more complete radiochemical analysis is required to determine that the sources of radiation exposure are within the limits of the Radiation Protection Guides.**

q. Rappahannock River Basin

The following effluent standards (adopted in Minute 17 from the proceedings of the Board at its meeting on September 17-18, 1972) apply to all waste discharges to the Rappahannock River Basin above the proposed Salem Church Dam in accordance with paragraphs a and b below:

CONSTITUENT	FINAL EFFLUENT REQUIREMENTS (WEEKLY AVERAGE)
BOD - mg/l	1
COD - mg/l	10
Suspended solids - mg/l	0 (unmeasurable)
MBAS - mg/l	0.1
Turbidity (Jackson Units)	0.4
Fecal Coliform Bacteria per 100 ml sample	Less than 2
Nitrogen - mg/l	1
Phosphorus - mg/l	0.1

a. **After the date of Congressional authorization for actual construction of the dam has been given, all new proposals shall comply fully with the adopted standards of paragraph (1) above and all existing owners shall immediately commence the necessary planning, financing and design to insure that facilities are completed prior to final completion of the construction of the dam, and**

b. **Any new proposals for waste discharges to the area encompassed by the standards shall provide such conventional treatment that in the opinion of the State Department of Health, the staff and the Board, satisfactory advanced waste treatment units can readily be added when funds for construction of the Salem Church Dam have been authorized.**

These effluent requirements will apply if the proposed Salem Church Dam is constructed, since, with the dam's construction, the Rappahannock River would be changed from a free-flowing stream to an impoundment which would serve, among other things, as a domestic water supply. The strict effluent limits were intended to prevent the water quality problems that can occur when wastewater with insufficient nutrient removal is discharged into an impoundment and to protect the impoundment's proposed use as a water supply.

The standards were proposed at a public hearing on September 29, 1971, and adopted in Minute 17 from the proceedings of the Board at its September 17-18, 1972 meeting.

r. Zinc (total) not to exceed 0.5 mg/l at any time.

s. Chlorides not to exceed 40 mg/l at any time.

t. **Chlorides not to exceed 8000 mg/l at any time.**

u. **Maximum temperature for the New River Basin from West Virginia State line upstream to the Giles - Montgomery County line:**

The maximum temperature shall be 27°C (81°F) unless caused by natural conditions; the maximum rise above natural temperatures shall not exceed 2.8°C (5°F).

This maximum temperature limit of 81°F was established in the 1970 water quality standards amendments so that Virginia temperature standards for the New River would be consistent with those of West Virginia since the stream flows into that state.

v. **The maximum temperature of the New River and its tributaries (except trout waters) from the Montgomery-Giles County line upstream to the Virginia-North Carolina State line shall be 29°C (84°F).**

w. **In Minute 3 from its meeting on March 10-11, 1977, the Board authorized a variance to the General Standard relating to zinc for the length of Ash Camp Creek and a portion of Little Roanoke Creek from the confluence of Ash Camp Creek to the Route 47 bridge.**

5.02 Scenic Rivers

The Designation of a Scenic River and the significance of this designation are the subject of the Scenic Rivers Act (Section 10-167 *et seq* of the Code of Virginia).

The listing of Scenic Rivers that follows imposes no additional Water Control Board requirements or standards. It is only a means to identify for this booklet those streams that have been included by the General Assembly in the Scenic Rivers System.

POTOMAC RIVER BASIN

Potomac River Subbasin

SR-1 Goose Creek from its confluence with the Potomac River upstream to the Fauqier-Loudoun County line (about 28 miles).

SR-2 Catoctin Creek in Loudoun County from its confluence with the Potomac River upstream to the Town of Waterford.

Shenandoah River Subbasin

SR-3 The Shenandoah River in Clark County from the Warren-Clark County line to Lockes Landing.

JAMES RIVER BASIN

SR-4 The Saint Marys River in Augusta County within the George Washington National Forest.

SR-5 Rivanna River from its confluence with the James River upstream to the Fluvanna-Albemarle County line.

SR-6 Appomattox River from the Route 36 bridge crossing in the City of Petersburg upstream to the abutment dam located about 1.3 miles below Lake Chesdin (about 5 miles).

ROANOKE RIVER BASIN

SR-7 Roanoke (Staunton) River from Brookneal upstream to Long Island.

CHOWAN AND DISMAL SWAMP BASIN

Chowan River Subbasin

SR-8 The Nottoway River in Sussex County from the Route 40 bridge at Stony Creek to the Southampton County line.

6. WATER QUALITY CRITERIA

In its 1977 amendments to Virginia's Water Quality Standards, the Board included the adoption of water quality criteria for certain substances in surface water and groundwater. These may be found in Sections 6.01 and 6.02 below.

Since there are differing interpretations of the term criteria, the Board's distinction between ***criteria*** and ***standards*** in its Water Quality Standards book should be explained. Both criteria and standards describe a desired degree of water quality either with narrative statements, or by numeric limits for specific substances. Criteria are ***recommended*** concentrations of substances that, when not exceeded, should generally protect the aquatic environment for aquatic life and various water uses with an adequate degree of safety. The Board-adopted criteria are guidelines only, which may serve as a base of information for various Board programs. They are not intended for direct regulatory use and should not be considered as absolute, mandatory requirements to maintain any specific degree of water quality. Criteria are not standards; they carry no regulatory mandate and must be justified independently in each application. Criteria differ from standards, which are legally enforceable water quality requirements adopted for a particular waterway. A ***standard*** has direct regulatory use - i.e., effluent limits placed in a discharge permit ***must ensure*** that water quality standards are met in the receiving stream. The Board will undoubtedly be developing standards in the future based on these criteria, but the actual values of the standards could be different from the criteria in the final analysis and adoption process.

6.01 Water Quality Criteria for Surface Water

Cadmium	5.0	ug/l - Class I and II waters
	0.4 ug/l - soft water* 1.2 ug/l - hard water	Class III, IV, V, and VI waters for cladocerans and salmonid fishes
	4.0 ug/l - soft water* 12.0 ug/l - hard water	Class III, IV, V, and VI waters for other less sensitive species
Chlorine	0.5	ug/l - Class I and II waters
	1.0	ug/l - Class III, IV, V, and VI waters
Chromium (total)	100	ug/l - All waters
Copper		0.1 times the 96-hour LC_{50} value as determined through nonaerated, continuous flow bioassay, using the receiving water or comparable water as the diluent and using a sensitive resident species
Cyanide	5.0	ug/l - All Waters
Iron	1.0	mg/l - Class III, IV, V, and VI waters
Lead		0.01 times the 96-hour LC_{50} value as determined through continuous flow bioassay, using the receiving or comparable water as the diluent and soluble lead measurements (non-filterable lead using an 0.45 micron filter), for sensitive freshwater fish species.
Manganese	100	ug/l - Class I and II waters
Mercury	0.10	ug/l - Class I and II waters
	0.05	ug/l - Class III, IV, V, and VI waters

***Soft water generally is considered to be less than 100 mg/l hardness as $CaCO_3$ and hard water generally is 100 mg/l $CaCO_3$ or greater.**

6.01 Water Quality Criteria for Surface Water (Contd.)

Nickel	0.01 times the 96-hour LC_{50} value as determined through continuous flow bioassay using the receiving or comparable water as the diluent and using a sensitive resident species
Phenol	1.0 ug/l - All waters
Phthalate Ester	3.0 ug/l - Class III, IV, V, and VI waters (3 ug/l is a goal for Class I and II waters pending additional effect data)
Polychlorinated biphenyls	Zero
Selenium	For marine and aquatic life 0.01 times the 96-hour LC_{50} value as determined through continuous flow bioassay using receiving or comparable dilution water and using a sensitive resident fish species.
Silver	Zero
Zinc	For freshwater aquatic life 0.01 times the 96-hour LC_{50} value as determined through continuous flow bioassay using receiving or comparable dilution water and using a sensitive resident species.
Nutrients	In impounded waters, the total phosphates as phosphorous (P) should not exceed 50 ug/l in any stream where it enters a lake or reservoir nor 25 ug/l within the lake or reservoir.
Oil and Grease	0.01 times the lowest continuous flow 96-hour LC_{50} value for several important freshwater and marine species, each having a demonstrated high susceptibility to oils and petrochemicals.

Pesticides

Aldrin/Dieldrin	0.003 ug/l - All waters
Chlordane	0.004 ug/l - Class I and II 0.01 ug/l - Class III, IV, V and VI waters
DDT	0.001 ug/l - All waters
Demeton	0.1 ug/l - All waters
Endosulfan	0.001 ug/l - Class I and II waters 0.003 ug/l - Class II, IV, V, and VI waters
Endrin	0.004 ug/l - All waters
Guthion	0.01 ug/l - All waters
Heptachlor	0.001 ug/l - All waters

6.01 Water Quality Criteria for Surface Water (Contd.)

Kepone	Zero
Lindane	0.004 ug/l - Class I and II waters 0.01 ug/l - Class III, IV, V, and VI waters
Malathion	0.1 ug/l - All waters
Methoxychlor	0.03 ug/l - All waters
Mirex	Zero
Parathion	0.04 ug/l - All waters
Toxaphene	Zero

6.02 Water Quality Criteria for Groundwater

These groundwater quality criteria apply primarily to groundwater constituents that occur naturally. Since natural groundwater quality can vary greatly from area to area for these constituents, enforceable standards were not adopted. These criteria are intended to provide guidance in preventing groundwater pollution. (For additional information about their development see page 9.) Groundwater criteria carry the same regulatory limitation as surface water criteria: they are not mandatory.

CONSTITUENT	UNITS	GROUNDWATER CRITERIA BY PHYSIOGRAPHIC PROVINCE***			
		Coastal Plain	Piedmont & Blue Ridge	Valley & Ridge	Cumberland Plateau
Alkalinity	(mg/l)	30-500	10-200	30-500	30-200
Total Dissolved Solids	(mg/l)	1000	250	500	500
Chloride	(mg/l)	50*	25	25	25
Sulfate	(mg/l)	50	25	100	150
Total Organic Carbon	(mg/l)	10	10	10	10
Color	(color units)	15	15	15	15
Iron	(mg/l)	0.3	0.3	0.3	0.01-10
Manganese	(mg/l)	0.05	0.05	0.05	0.01- 0.5
Sodium	(mg/l)	100*	25	25	100
Fluoride	(mg/l)	1.4**	1.4	1.4	1.4
Hardness	(mg/l)	120	120	300	180

***It is recognized that naturally occurring concentrations will exceed this limit in the eastern part of the Coastal Plain, especially toward the shoreline and with increased depth.**

****Except within the cretaceous aquifer: concentration up to 5 mg/l and higher.**

*****See map, page 11, for delineation of physiographic provinces.**
