With regard to the future projections of global climate change, the proposed rule and supporting documents assumed that AR4's highest-emission scenario A1FI was the most likely. As discussed in Global Climate Change—General Overview, we assume that for corals RCP8.5 is the most impactful pathway for present to the year 2100. Ocean warming projections and implications for coral reefs are described above in the RCP8.5 Projections section.

Comment 12 also criticized our lack of consideration of the post-1998 hiatus in global warming. The proposed rule did not consider this phenomenon as the issue was only emerging during the time the proposed rule was drafted. However, because supplemental information has become available since that time, we consider it here. Despite unprecedented levels of GHG emissions in recent years, a slow-down in global

mean surface air temperature warming has occurred since 1998, which AR5's WGI refers to as a "hiatus." Despite this slowdown in warming, the period since 1998 is the warmest recorded and "Each of the last three decades has been successively warmer at the Earth's surface than any preceding decade since 1850."

The slow-down in global mean surface warming since 1998 is not fully explained by AR4 or AR5 WGI's models, but is consistent with the substantial decadal and interannual variability seen in the instrumental record and may result, in part, from the selection of beginning and end dates for such analyses. Possible factors in the slow-down may include the following: Heat absorption by the deep ocean (Guemas *et al.*, 2013; Levitus *et al.*, 2012) facilitated by stronger than normal trade winds (England *et al.*, 2014), volcanic eruptions over the last decade (Santer *et al.*, 2014), La Niña-like decadal cooling that produces multi-year periods of slower warming than the long-term anthropogenic forced warming trend (Benestad, 2012; Easterling and Wehner, 2009; Kosaka and Xie, 2013), inherent variability within the climate system that cannot currently be modeled, and potentially other factors (IPCC, 2013). As explained above, the major sources of uncertainty in climate change projections such as AR4 or AR5's WGI are: (1) The projected rate of increase for GHG concentrations; (2) strength of the climate's response to GHG concentrations; and (3) large natural variations. The slow-down in warming since 1998 is an example of a large natural variation that could not be predicted, at least by the models at that time.

Comment 12 identified several sources of spatial variability in ocean warming and requested our consideration of additional information. The proposed rule acknowledged both spatial and temporal variability in ocean warming and considered the effect that variability would have on the proposed corals. However, we acknowledge that supplemental information has since become available, and we consider it here. Regional and local variability in ocean warming conditions may lead to warming-induced bleaching that is more or less severe regionally or locally than globally. A hot spot of ocean warming occurs in the equatorial western Pacific where regional warming is higher than overall warming in the Indo-Pacific, exposing corals and coral reefs in this area to a higher risk of warming-induced bleaching. The hot spot overlaps the Coral Triangle (Couce *et al.*, 2013b; Lough, 2012; Teneva *et al.*, 2012; van

Hooidonk *et al.*, 2013b). Several other areas in the Indo-Pacific have been identified as having lower than average warming, including the western Indian Ocean, Thailand, the southern GBR, central French Polynesia, and the eastern equatorial Pacific, potentially resulting in relatively lower risk of warming-induced coral bleaching in these areas (Couce *et al.*, 2013b; van Hooidonk *et al.*, 2013b). Spatial variability in ocean warming is lower in the much smaller Caribbean, and there are fewer areas there with lower than average warming (Buddemeier *et al.*, 2011). The regional and local heterogeneity in ocean warming likely results in high variability in coral responses across spatial scales (Selig *et al.*, 2010).

There are several types of temporal variability in ocean warming on coral reefs. First, the rate of ocean warming itself changes over time. For example, ocean warming has increased in the Indo-Pacific since 1950, but at different rates at different times (Lough, 2012). Second, different periods of ocean warming can result in variability in warming-induced bleaching at the same location. For example, a study in Thailand showed significant differences in the susceptibility of coral taxa to bleaching events between the years 1998 and 2010 and among coral species at the same site (Sutthacheep *et al.*, 2013). Spatial variability in ocean warming between sites also results in temporal variability in ocean warming impacts, as the different areas are subsequently affected at different rates into the future (van Hooidonk *et al.*, 2013b). For example, a recent study found that Australian subtropical reef-building coral communities are affected by ocean warming more slowly than tropical reef-building coral communities, resulting in slower rates of changes in the subtropical than tropical communities (Dalton and Roff, 2013). These studies underscore the temporal variability of ocean warming and warming-induced bleaching across the ranges of reef-building coral species, complicating the interpretation of the effects of ocean warming on any given coral species across its range and over time.

Mesophotic and marginal habitats serving as refugia from ocean warming are relatively new and potentially important considerations for the vulnerability of coral species to ocean warming. Mesophotic habitats continue to be explored, with new surveys finding larger habitat areas and greater depth distributions for some reef-building corals (Blyth-Skyrme *et al.*, 2013; Bridge and Guinotte, 2012). Supplemental information demonstrates

the potential for mesophotic habitat to provide refugia from ocean warming (Bridge *et al.*, 2013a; Smith *et al.*, in press), although it does not always do so (Neal *et al.*, 2013). Marginal habitats, such as high latitude sites, upwelling regions, and turbid areas like the GBR inner shelf, also may provide refugia from ocean warming for some species in some conditions (Browne *et al.*, 2012; Couce *et al.*, 2013b; Dalton and Roff, 2013), but not others (Lybolt *et al.*, 2011). Taken together, mesophotic and marginal habitats may represent a network of refugia from ocean warming for some species.

Comment 14 emphasized both that coral reefs are likely to decline sharply in the future because of increasing GHG emissions (*e.g.*, Carpenter *et al.*, 2008; Donner, 2009; Frieler *et al.*, 2012; Kiessling and Baron-Szabo, 2004) and that a wide range of responses by coral reef ecosystems are possible. Studies provided by commenters, and others on recent modeling results (Frieler *et al.*, 2012; van Hooidonk and Huber, 2012; van Hooidonk *et al.*, 2013b) and scientific opinion statements (Birkeland *et al.*, 2013; ICRS, 2012) suggest disastrous effects of ocean warming, in combination with other threats, on coral reef ecosystems. For example, even in AR5 WGI's best-case pathway (RCP2.6) where CO<sub>2</sub> equivalent concentrations peak at 455 ppm, one model suggests that 95 percent of coral reefs will experience annual bleaching conditions by the end of the century (van Hooidonk *et al.* 2013b). Another model suggests that preserving more than 10 percent of coral reefs worldwide would require limiting warming to less than 1.5 °C above pre-industrial levels. Even assuming high adaptive capacity of corals and the more optimistic AR5 pathways, the model suggests that one-third of the world's coral reefs are projected to be subject to long-term degradation (Frieler *et al.*, 2012). In addition, the combined effects of ocean warming and ocean acidification would produce even more severe impacts on coral reefs globally (van Hooidonk *et al.*, 2013a; Yara *et al.*, 2012).

These and other studies predict the irreversible disappearance of coral reefs on a global scale in the next few decades. However, other recent studies suggest that coral reef degradation resulting from global climate change threats alone is likely to be a more spatially, temporally, and taxonomically heterogeneous process. These studies indicate that coral reef ecosystems, rather than disappear entirely as a result of future impacts, will likely persist, but with unpredictable changes in the composition of coral species and

ecological functions (Hughes *et al.*, 2012; Pandolfi *et al.*, 2011). Many factors contribute to the heterogeneous responses of coral reefs to climate change threats, including complexity associated with coral reef habitat, as well as the biology of reef-building coral species themselves. As described in the Corals and Coral Reefs section, the exceptional complexity, extent, and diversity of coral reef habitat increases the uncertainty associated with coarse modeling of reef responses to climate change threats. Likewise, many aspects of reef-building coral biology contribute to complex responses to ocean warming, including species-level processes such as capacity for acclimatization and adaptation (Palumbi *et al.*, 2014), the potential for range expansion (Yamano *et al.*, 2011; Yara *et al.*, 2011), and community-level processes such as changes in competition and predation (Cahill *et al.*, 2013; Hughes *et al.*, 2012). These different processes occur simultaneously, and contribute to highly-variable, complex, and uncertain responses of reef-building coral species and in turn coral reefs to climate changes threats like ocean warming. Moreover, management of local threats can increase resilience of coral reefs to ocean warming and other global climate change threats (Jackson *et al.*, 2014; Pandolfi *et al.*, 2011), as described further in the Threats Evaluation—Inadequacy of Existing Regulatory Mechanisms section.

Comment 15 focused on the specific effects of ocean warming on reef-building corals. The proposed rule described the known specific effects of ocean warming as well as the threats that act simultaneously or sequentially, and whether the effects are cumulative (the sum of individual stresses) or interactive (*e.g.*, synergistic or antagonistic). The rapidly growing literature on synergistic effects of ocean warming-induced bleaching with other threats demonstrates that bleaching is exacerbated by nutrients (Cunning and Baker, 2013; Vega Thurber *et al.*, 2013; Wiedenmann *et al.*, 2013), disease is exacerbated by warm temperatures and bleaching (Ban *et al.*, 2013; Bruno *et al.*, 2007; Muller and van Woosik, 2012; Rogers and Muller, 2012), ocean warming and acidification may impact corals in opposite but converging ways (van Hooidonk *et al.*, 2013a; Yara *et al.*, 2012), and bleaching is exacerbated by a variety of physical factors (Yee and Barron, 2010) or can be reduced by biological factors (Connolly *et al.*, 2012; Fabricius *et al.*, 2013). Other information on species-specific effects of ocean warming is provided in the

Species-specific Information and Determinations section below.

Comment 15 focused on the potential capacity of reef-building corals for acclimatization and adaptation to ocean warming and provided several new studies (Cahill *et al.*, 2013; Guest *et al.*, 2012; Jones and Berkelmans, 2010) and some that we considered in the proposed rule (Baker *et al.*, 2004; Maynard *et al.*, 2008; Pandolfi *et al.*, 2011). Identified mechanisms include symbiont shuffling (Baker, 2012; Cuning *et al.*, 2013; Ortiz *et al.*, 2013; Silverstein *et al.*, 2012), symbiont shading by host pigments or tissue (Mayfield *et al.*, 2013; Smith *et al.*, 2013a), host genotype expression (Baums *et al.*, 2013; Granados-Cifuentes *et al.*, 2013; Meyer *et al.*, 2011), and host protein expression (Barshis *et al.*, 2013; Voolstra *et al.*, 2011). As described in the Corals and Coral Reefs section, the dynamic association of host coral and symbiotic zooxanthellae and microbes provides potential for acclimatization or adaptation of some reef-building coral species to environmental changes.

Many recent studies provide evidence that certain reef-building coral communities have acclimated or adapted to ocean warming, at least to some degree. The bleaching and mortality of some colonies of a coral species on a reef, followed by the recovery of hardier colonies, is the process by which acclimatization and adaptation of a species to ocean warming occurs. Examples of bleaching, mortality, and recovery provide information about the capacity for acclimatization and adaptation. Several such examples were provided in the proposed rule and supporting documents (Diaz-Pulido *et al.*, 2009; Hueerkamp *et al.*, 2001; Kayanne *et al.*, 2002). More recently, many relevant studies have become available on the effects of the 1998 bleaching event. For example, in comparisons of 1998 and 2010 bleaching events and recovery in southeast Asia, some coral species demonstrated more resistance to bleaching in 2010, suggesting acclimatization or adaptation to thermal stress (Sutthacheep *et al.*, 2013). In a study on an isolated reef in Australia, recovery of coral cover occurred within 12 years of the 1998 bleaching event (Gilmour *et al.*, 2013). In contrast, studies in the U.S. Virgin Islands and Florida demonstrated little if any recovery in the 10 to 12 years following the 1998 bleaching event (Rogers and Muller, 2012; Ruzicka *et al.*, 2013).

A recent analysis comparing observed versus predicted coral bleaching events suggests that corals may have already responded adaptively to some warming

since the Industrial Revolution because observed bleaching responses are lower than predicted by the warm temperature anomalies (Logan *et al.*, 2013). A recent study of fast-growing, shallow water coral species demonstrated that acclimatization and adaptive responses allowed them to inhabit reef areas with water temperatures far above their expected tolerances (Palumbi *et al.*, 2014). Similar to the mechanisms of coral acclimatization and adaptation described above, there is a rapidly growing body of literature on the responses of corals to ocean warming (Ateweberhan *et al.*, 2013; Baker *et al.*, 2013; Bellantuono *et al.*, 2012; Castillo *et al.*, 2012; Coles and Riegl, 2013; Penin *et al.*, 2013). These studies help explain the capacity for reef-building corals to acclimatize and adapt to ocean warming and warming-induced bleaching and suggest some limited capacity. However, any such capacity is highly dependent on species, location, habitat type, and many other factors. Available species-specific information on vulnerability to ocean warming and warming-induced bleaching, including evidence of acclimatization or adaptation, is provided in the Species-specific Information and Determination sections below.

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding ocean warming remains unchanged from the proposed rule, in that we consider ocean warming to be of high importance in contributing to extinction risk for the 65 corals in this final rule. However, we acknowledge that the interpretation of future ocean warming and warming-induced impacts to corals and coral reefs is associated with complexity and uncertainty, and that precise effects on individual species of reef-building corals are especially difficult to determine. The impact of ocean warming may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by ocean warming depends on its particular level of susceptibility, combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is discussed in detail for each species in the Species-specific Information and Determinations section.

*Disease (High Importance Threat, ESA Factor C)*

Disease is considered under ESA Factor C—disease or predation. In the proposed rule we described the threat of disease as follows. Disease adversely

affects various coral life history events by, among other processes, causing adult mortality, reducing sexual and asexual reproductive success, and impairing colony growth. A diseased state results from a complex interplay of factors including the cause or agent (*e.g.*, pathogen, environmental toxicant), the host, and the environment. All coral disease impacts are presumed to be attributable to infectious diseases or to poorly-described genetic defects. Coral disease often produces acute tissue loss. Other manifestations of disease in the broader sense, such as coral bleaching from ocean warming, are incorporated under other factors (*e.g.*, manmade factors such as ocean warming as a result of climate change).

Coral diseases are a common and significant threat affecting most or all coral species and regions to some degree, although the scientific understanding of individual disease causes in corals remains very poor. The incidence of coral disease appears to be expanding geographically in the Indo-Pacific, and there is evidence that corals with massive morphology species are not recovering from disease events in certain locations. The prevalence of disease is highly variable between sites and species. Increased prevalence and severity of diseases is correlated with increased water temperatures, which may correspond to increased virulence of pathogens, decreased resistance of hosts, or both. Moreover, the expanding coral disease threat may result from opportunistic pathogens that become damaging only in situations where the host integrity is compromised by physiological stress or immune suppression. Overall, there is mounting evidence that warming temperatures and coral bleaching responses are linked (albeit with mixed correlations) with increased coral disease prevalence and mortality. Complex aspects of temperature regimes, including winter and summer extremes, may influence disease outbreaks. Bleaching and coral abundance seem to increase the susceptibility of corals to disease contraction. Further, most recent research shows strong correlations between elevated human population density in close proximity to coral reefs and disease prevalence in corals.

Although disease causes in corals remain poorly understood, some general patterns of biological susceptibility are beginning to emerge. There appear to be predictable patterns of immune capacity across coral families, corresponding with trade-offs with their life history traits, such as reproductive output and growth rate. Both Acroporidae and Pocilloporidae have low immunity to

disease. However, both of these families have intermediate to high reproductive outputs. Both Faviidae and Mussidae are intermediate to high in terms of disease immunity and reproductive output. Finally, while Poritidae has high immunity to disease, it has a low reproductive output.

The effects of coral disease depend on exposure of the species to the threat, which varies spatially across the range of the species and temporally over time. Exposure to coral disease is moderated by distance of some coral habitats from the primary causes of most disease outbreaks, such as stressors resulting from sedimentation and nutrient over-enrichment. Exposure to coral disease can also be moderated by depth of many habitats, with deep habitats generally being less affected by disease outbreaks associated with stressors resulting from ocean warming. Disease exposure in remote areas and deep habitats appears to be low but gradually increasing. Exposure to coral disease will increase as factors that increase disease outbreaks (e.g., warming events) expand over time.

As explained above, disease may be caused by threats such as ocean warming and bleaching, nutrients, and toxins. However, interactive effects between independently-arising disease and other threats are also important, because diseased colonies are more susceptible to the effects of some other threats. For example, diseased or recovering colonies may become more quickly stressed than healthy colonies by land-based sources of pollution (sedimentation, nutrients, and toxins), may more quickly succumb to predators, and may more easily break during storms or as a result of other physical impacts.

Comments 17 and 18 discussed the importance of disease as a threat to corals and provided a few scientific studies (Harvell *et al.*, 1999; Harvell *et al.*, 2002; Muller and van Woesik, 2012; Rogers and Muller, 2012) to emphasize this importance. Muller and van Woesik (2012) examined spatial epidemiology in the Caribbean to test if pathogens are contagious and spread from infected to susceptible hosts. They found no evidence of clustering for these diseases, so they did not follow a contagious disease model. They suggest the expression of coral disease is a two-step model: Environmental thresholds are exceeded, then those conditions either weaken the coral or increase the virulence of the pathogen (Muller and van Woesik, 2012).

We also gathered supplemental information on the threat of disease since the proposed rule was published.

Burge *et al.* (2014) summarized the current understanding of interactions among coral disease, elevated temperature, and bleaching. This supplemental information provides further insight of coral disease impacts at the individual level and the local aggregation level, and provides future predictions for the role of coral disease at the population level.

At the individual level, recent studies examine both underlying factors and mechanistic explanations for the contraction and expansion of coral disease. For example, one study investigated microbial community dynamics in the mucus layer of corals to understand how the surface microbial community responds to changes in environmental conditions and under what circumstances it becomes vulnerable to overgrowth by pathogens. They found that a transient thermal anomaly can cause the microbial community to shift from a stable state dominated by antibiotic microbes to a stable state dominated by pathogens. Beneficial microbes may not be able to resume dominance after a temperature disturbance until the environment becomes considerably more favorable for them (Mao-Jones *et al.*, 2010). Another study conducted a meta-analysis to determine whether the presence of particular microbial taxa correlates with the state of coral health and found distinct differences in the microbial taxa present in diseased and healthy corals (Mouchka *et al.*, 2010). A third study investigated three variables commonly associated with immunity in hard and soft corals spanning ten families on the GBR. They found that all three variables (phenyloxidase activity, size of melanin containing granular cells, and fluorescent protein concentrations) were significant predictors of susceptibility (Palmer *et al.*, 2010). Many other studies have focused on bacterial or eukaryotic pathogens as the source of coral disease; however, a more recent study examined the role of viruses and determined that a specific group of viruses is associated with diseased Caribbean corals (Soffer *et al.*, 2013).

Several studies provide further evidence of disease outbreaks that were significantly correlated with bleaching events. The bleaching occurred first, then several months to a year later, there were significant increases in disease prevalence in bleached areas (Ban *et al.*, 2013; Brandt and McManus, 2009; Bruno *et al.*, 2007; Croquer *et al.*, 2006; Croquer and Weil, 2009; Miller *et al.*, 2009). The specific interactions between the two phenomena varied among disease-bleaching combinations. Results

from one of these studies suggest the hypothesized relationship between bleaching and disease events may be weaker than previously thought, and more likely to be driven by common responses to environmental stressors, rather than directly facilitating one another.

Ateweberhan *et al.* (2013) reviewed and summarized interactions between important threats to corals. They note that disease can interact not only with ocean warming and bleaching events, but may also be exacerbated by sedimentation, nutrients, overfishing, and destructive practices on coral reefs. From a broad, population-wide perspective, Yakob and Mumby (2011) provide an important alternative context in which to demonstrate that high population turnover within novel ecosystems (those that are different from the past and created by climate change) may enhance coral resistance to disease. They emphasize the need to move away from future projections based on historical trends and start to account for novel behavior of ecosystems under climate change.

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding disease remains unchanged from the proposed rule, in that we consider coral disease to be of high importance in contributing to extinction risk for the 65 corals in this final rule. The impact of disease may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by disease depends on its particular level of susceptibility, combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is discussed in detail for each species in the Species-specific Information and Determinations section.

#### *Ocean Acidification (Medium-High Importance Threat, ESA Factor E)*

Ocean acidification is considered under ESA Factor E—other natural or manmade factors affecting the continued existence of the species—because the effect is a result of human activity and affects individuals of the coral species more so than their habitats. In the proposed rule we described that ocean acidification is a result of global climate change caused by increased GHG accumulation in the atmosphere. Reef-building corals produce skeletons made of the aragonite form of calcium carbonate; thus, reductions in aragonite saturation state caused by ocean acidification pose a major threat to these species and other

marine calcifiers. Ocean acidification has the potential to cause substantial reduction in coral calcification and reef cementation. Further, ocean acidification adversely affects adult growth rates and fecundity, fertilization, pelagic planula settlement, polyp development, and juvenile growth. The impacts of ocean acidification can lead to increased colony breakage and fragmentation and mortality. Based on observations in areas with naturally low pH, the effects of increasing ocean acidification may also include potential reductions in coral size, cover, diversity, and structural complexity.

As CO<sub>2</sub> concentrations increase in the atmosphere, more CO<sub>2</sub> is absorbed by the oceans, causing lower pH and reduced availability of carbonate ions, which in turn results in lower aragonite saturation state in seawater. Because of the increase in CO<sub>2</sub> and other GHGs in the atmosphere since the Industrial Revolution, ocean acidification has already occurred throughout the world's oceans, including in the Caribbean and Indo-Pacific, and is predicted to considerably increase between now and 2100, as described above in the RCP8.5 Projections section. Along with ocean warming and disease, we considered ocean acidification to be one of the most important threats posing extinction risks to coral species between now and the year 2100; however, individual susceptibility varies among the proposed species.

Numerous laboratory and field experiments have shown a relationship between elevated CO<sub>2</sub> and decreased calcification rates in some corals and other calcium carbonate secreting organisms. However, because only a few species have been tested for such effects, it is uncertain how most will fare in increasingly acidified oceans. In addition to laboratory studies, recent field studies have demonstrated a decline in linear growth rates of some coral species, suggesting that ocean acidification is already significantly reducing growth of corals on reefs. However, this has not been widely demonstrated across coral species and reef locations, suggesting species-specific effects and localized variability in aragonite saturation state. A potential secondary effect is that ocean acidification may reduce the threshold at which bleaching occurs. Overall, the best available information demonstrates that most corals exhibit declining calcification rates with rising CO<sub>2</sub> concentrations, declining pH, and declining aragonite saturation state, although the rate and mode of decline can vary among species. Recent studies also discuss the physiological effects of

ocean acidification on corals and their responses. Corals are able to regulate pH within their tissues, maintaining higher pH values in their tissues than the pH of surrounding waters. This is an important mechanism in naturally highly-fluctuating environments (*e.g.*, many backreef pools have diurnally fluctuating pH) and suggests that corals have some adaptive capacity to acidification. However, as with ocean warming, there is high uncertainty as to whether corals will be able to adapt quickly enough to the projected changes in aragonite saturation state.

In addition to the direct effects on coral calcification and growth, ocean acidification may also affect coral recruitment, reef cementation, and other important reef-building species like crustose coralline algae. Studies suggest that the low pH associated with ocean acidification may impact coral larvae in several ways, including reduced survival and recruitment. Ocean acidification may influence settlement of coral larvae on coral reefs more by indirect alterations of the benthic community, which provides settlement cues, than by direct physiological disruption. A major potential impact from ocean acidification is a reduction in the structural stability of corals and reefs, which results both from increases in bioerosion and decreases in reef cementation. As atmospheric CO<sub>2</sub> rises globally, reef-building corals are expected to calcify more slowly and become more fragile. Declining growth rates of crustose coralline algae may facilitate increased bioerosion of coral reefs from ocean acidification. Studies demonstrate that ocean acidification will likely have a great impact on corals and reef communities by affecting community composition and dynamics, exacerbating the effects of disease and other stressors (*e.g.*, temperature), contributing to habitat loss, and affecting symbiont function. Some studies have found that an atmospheric CO<sub>2</sub>-level twice as high as pre-industrial levels will start to dissolve coral reefs; this level could be reached as early as the middle of this century. Further, the rate of acidification may be an order of magnitude faster than what occurred 55 million years ago during the Paleocene-Eocene Thermal Maximum (*i.e.*, the period in which global temperatures rose 5 to 9 °C, providing a context in which to understand climate change).

While CO<sub>2</sub> levels in the surface waters of the ocean are generally in equilibrium with the lower atmosphere, there can be considerable variability in seawater pH across reef-building coral habitats, resulting in colonies of a species experiencing high spatial variability in

exposure to ocean acidification. The spatial variability in seawater pH occurs from reef to global scales, driven by numerous physical and biological characteristics and processes, including: Seawater temperature; proximity to land-based runoff and seeps; proximity to sources of oceanic CO<sub>2</sub>; salinity; nutrients; photosynthesis; and respiration. In cooler waters, CO<sub>2</sub> absorption is higher, driving pH and aragonite saturation state lower, thus relatively cool coral habitats are more susceptible to acidification, such as those at higher latitudes, in upwelling areas, and in deeper environments. On coral reefs, wave and wind-induced mixing typically maintain roughly similar temperatures in the shallow photic zone preferred by most reef-building corals, thus the deeper environments that are more susceptible to acidification are generally below this photic zone.

Land-based runoff decreases salinity and increases nutrients, both of which can raise pH. Local sources of oceanic CO<sub>2</sub> like upwelling and volcanic seeps lower pH. Photosynthesis in algae and seagrass beds draws down CO<sub>2</sub>, raising pH. High variability over various time-scales is produced by numerous processes, including diurnal cycles of photosynthesis and respiration, seasonal variability in seawater temperatures, and decadal cycles in upwelling. Temporal variability in pH can be very high diurnally in highly-fluctuating or semi-enclosed habitats such as reef flats and back-reef pools, due to high photosynthesis during the day (pH goes up) and high respiration during the night (pH goes down). In fact, pH fluctuations during one 24-hr period in such reef-building coral habitats can exceed the magnitude of change expected by 2100 in open ocean subtropical and tropical waters. As with spatial variability in exposure to ocean warming, temporal variability in exposure to ocean acidification is a combination of high variability over short time-scales together with long-term increases. While exposure of the proposed coral species to ocean acidification varies greatly both spatially and temporally, it is expected to increase for all species across their ranges between now and 2100.

Ocean acidification likely interacts with other threats, especially considering that ocean acidification is expected to continue to increase over the foreseeable future. For example, ocean acidification may reduce the threshold at which bleaching occurs, increasing the threat posed by ocean warming. One of the key impacts of ocean acidification is reduced

calcification, resulting in reduced skeletal growth and skeletal density, which may lead to numerous interactive effects with other threats. Reduced skeletal growth compromises the ability of coral colonies to compete for space against algae, which grows more quickly as nutrient over-enrichment increases, especially if not held in check by herbivores. Reduced skeletal density weakens coral skeletons, resulting in greater colony breakage from natural and human-induced physical damage.

As discussed in Comments 18–21, we received numerous comments related to the threat to corals from ocean acidification including: (1) The overview and future projections of ocean acidification; (2) variability in ocean acidification; and (3) specific effects of ocean acidification on reef-building corals.

Comment 17 stated that we oversimplified the complexity and variability in the future projections of ocean acidification, and criticized our reliance on AR4 as the basis for our threat evaluation. In the proposed rule, we acknowledged the uncertainty associated with projections of ocean acidification from global climate change. However, while there are many sources of uncertainty in climate change projections, and likewise for ocean acidification, the ocean acidification projections in AR4 and AR5's WGI represent the best available information. The proposed rule and supporting documents assumed that AR4's highest-emission scenario A1F1 was the most likely to occur. Now that AR5's WGI is available, we consider the most impactful pathway to coral is WGI's RCP8.5, which includes ocean acidification projections. These projections are described above in the RCP8.5 Projections section, along with two independent analyses of the effects of ocean acidification projections in RCP8.5 on coral reefs in the 21st century. As noted in the RCP8.5 Projections section, there is uncertainty in these ocean acidification projections for coral reefs.

Comment 18 specifically cites Manzello *et al.* (2012) and Palacios and Zimmerman (2012; 2007) to illustrate that variability in ocean acidification on coral reefs can be buffered by local and regional biogeochemical processes within seagrass beds. Additionally, biogeochemical processes within coral reef communities (Andersson *et al.*, 2013) may buffer the effects of decreasing pH. Other scientific studies identify mechanisms that can exacerbate changes in seawater pH around coral reefs from ocean acidification, such as diurnal variability that can amplify CO<sub>2</sub>

in seawater around coral reefs (Shaw *et al.*, 2013). On larger scales, a recent study demonstrated that some coastal areas of the Gulf of Mexico and South Atlantic were buffered against ocean acidification because of the input of fresh, alkaline surface waters carrying dissolved inorganic carbon (Wang *et al.*, 2013). Variability in ocean acidification at basin and global scales is influenced largely by upwelling and latitude, with more acidification in areas of high upwelling and lower temperatures. The interaction of ocean acidification with ocean warming produces basin-level patterns of higher and lower habitat suitability for reef-building corals (Couce *et al.*, 2013b; van Hooijdonk *et al.*, 2013a; Yara *et al.*, 2012).

Comments 19 and 20 underscore specific effects to corals from ocean acidification identified in the proposed rule, including: (1) Effects on reef accretion; (2) effects on larvae and juvenile corals; (3) interactive effects with other environmental variables; and (4) miscellaneous effects. Recent research identifies impacts of ocean acidification on reef accretion due to reduced coral calcification (Chan and Connolly, 2013) and impacts on crustose coralline algae (Doropoulos and Diaz-Pulido, 2013). Recent research has also found that impacts of ocean acidification on brooded larvae of *Pocillopora damicornis* were higher when the larvae were released earlier (Cumbo *et al.*, 2013) and that nutritionally replete juvenile corals were less susceptible to ocean acidification than nutritionally deprived juveniles (Drenkard *et al.*, 2013).

Many recent studies have investigated the interactive effects of ocean acidification with other environmental variables. The opposing effects of ocean warming and ocean acidification were discussed in a study that demonstrated low light conditions can exacerbate ocean acidification effects. Low-light conditions can provide a refuge for reef-building corals from thermal and light stress, but this study suggests that lower light availability will potentially increase the susceptibility of key coral species to ocean acidification (Suggett *et al.*, 2013). Another study predicts that increasing storms predicted by climate change, together with ocean acidification, are likely to increase collapse of table corals (Madin *et al.*, 2012). Salinity extremes on a nearshore coral community did not affect the sensitivity of reef-building corals to ocean acidification (Okazaki *et al.*, 2013). Finally, several studies have investigated the simultaneous effects of ocean warming and ocean acidification, most of which have found harmful

synergistic effects (Ateweberhan *et al.*, 2013; Dove *et al.*, 2013; Kroeker *et al.*, 2013), but not all (Wall *et al.*, 2013). However, impacts of ocean acidification are more rapid in cool water, such as in mesophotic habitat (Cerrano *et al.*, 2013) and temperate areas (Yara *et al.*, 2012).

Several other recent papers also provide information on the impacts of ocean acidification on reef-building corals. A study of the effects of ocean acidification on primary polyps with and without zooxanthellae found that polyps with zooxanthellae had higher tolerance to ocean acidification, suggesting that coral species that acquire symbionts from the environment will be more vulnerable to ocean acidification than corals that maternally acquire symbionts (*i.e.*, brooding species; Ohki *et al.*, 2013). A study of *Porites* corals at a field site with naturally low pH found that the corals were not able to acclimatize enough to prevent the impacts of local ocean acidification on their skeletal growth and development, despite spending their entire lifespan in low pH seawater (Crook *et al.*, 2013). A study of the effects of ocean acidification on different coral species in different environments found that effects were highly species-dependent, and furthermore, that effects within a species depended on the environment (Kroeker *et al.*, 2013).

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding ocean acidification remains unchanged from the proposed rule, in that we consider ocean acidification to be of medium-high importance in contributing to extinction risk for the 65 corals in this final rule. However, we acknowledge that the interpretation of future ocean acidification and acidification-induced impacts to corals and coral reefs is associated with complexity and uncertainty and that the effects on individual species of reef-building corals are especially difficult to determine. The impact of ocean acidification may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by ocean acidification depends on its particular level of susceptibility, combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is discussed in detail for each species in the Species-specific Information and Determinations section.

*Trophic Effects of Fishing (Medium Importance Threat, ESA Factor A)*

Trophic effects of fishing are considered under ESA Factor A—the present or threatened destruction, modification, or curtailment of its habitat or range—because the main effect of concern is to limit availability of habitat for corals. In the proposed rule we described the threat of the trophic effects of reef fishing as follows. Fishing, particularly overfishing, can have large scale, long-term ecosystem-level effects that can change ecosystem structure from coral-dominated reefs to algal-dominated reefs (“phase shifts”). Even fishing pressure that doesn’t rise to the level of overfishing potentially can alter trophic interactions that are important in structuring coral reef ecosystems. These trophic interactions include reducing population abundance of herbivorous fish species that control algal growth, limiting the size structure of fish populations, reducing species richness of herbivorous fish, and releasing corallivores from predator control. Thus, an important aspect of maintaining resilience in coral reef ecosystems is to sustain populations of herbivores, especially the larger scarine herbivorous wrasses such as parrotfish.

On topographically complex reefs, population densities can average well over a million herbivorous fishes per km<sup>2</sup>, and standing stocks can reach 45 metric tons per km<sup>2</sup>. In the Caribbean, parrotfishes can graze at rates of more than 150,000 bites per square meter per day, and thereby remove up to 90–100 percent of the daily primary production (e.g., algae). Under these conditions of topographic complexity with substantial populations of herbivorous fishes, as long as the cover of living coral is high and resistant to mortality from environmental changes, it is very unlikely that the algae will take over and dominate the substrate. However, if herbivorous fish populations, particularly large-bodied parrotfish, are heavily fished and a major mortality of coral colonies occurs, then algae can grow rapidly and prevent the recovery of the coral population. The ecosystem can then collapse into an alternative stable state, a persistent phase shift in which algae replace corals as the dominant reef species. Although algae can have negative effects on adult coral colonies (e.g., overgrowth, bleaching from toxic compounds), the ecosystem-level effects of algae are primarily from inhibited coral recruitment. Filamentous algae can prevent the colonization of the substrate by planula larvae by creating sediment traps that obstruct access to a hard substrate for

attachment. Additionally, macroalgae can suppress the successful colonization of the substrate by corals through occupation of the available space, shading, abrasion, chemical poisoning, and infection with bacterial disease.

Overfishing can have further impacts on coral mortality via trophic cascades. In general larger fish are targeted, resulting in fish populations of small individuals. For parrotfishes, the effect of grazing by individuals greater than 20 cm in length is substantially greater than that by smaller fish. Up to 75 individual parrotfishes with lengths of about 15 cm are necessary to have the same reduction in algae and promotion of coral recruitment as a single individual 35 cm in length. Species richness of the herbivorous fish population is also very beneficial to maintaining available substrate potentially leading to enhanced coral populations. Because of differences in their feeding behaviors, several species of herbivorous fishes with complementary feeding behaviors can have a substantially greater positive effect than a similar biomass of a single species on reducing the standing stock of macroalgae, of increasing the cover of crustose coralline algae, and increasing live coral cover.

Exposure to the trophic effects of fishing in the Caribbean may be moderated by distance of some coral habitats from fishing effort. Exposure to the trophic effects of fishing in the Indo-Pacific is likely more moderated by distance than in the Caribbean, due to a greater proportion of reef-building coral habitats located in remote areas away from fishing effort. Exposure to the trophic effects of reef fishing may also be moderated by depth of many habitats in both regions, but again more so in the Indo-Pacific than in the Caribbean. Deep habitats are generally less affected by the trophic effects of fishing, especially in the Indo-Pacific. Exposure to the trophic effects of fishing will increase as the human population increases over time.

The trophic effects of fishing are likely to interact with many other threats, especially considering that fishing impacts are likely to increase within the ranges of many of the proposed corals over the foreseeable future. For example, when carnivorous fishes are overfished, corallivore populations may increase, resulting in greater predation on corals. Further, overfishing appears to increase the frequency of coral disease. Fishing activity usually targets the larger apex predators. When predators are removed, corallivorous butterfly fishes become more abundant and can transmit disease

from one coral colony to another as they transit and consume from each coral colony. With increasing abundance, they transmit disease to higher proportions of the corals within the population.

Comments 21–23 focused on the following aspects of the trophic effects of reef fishing: (1) The importance of the threat to coral reefs; (2) higher importance localized threats; and (3) consideration of human demography.

Comment 21 highlighted Keller *et al.* (2009), which provides additional support for the importance herbivores play in the maintenance of recruitment habitat. Further, recent information shows that one of the most detrimental effects of unsustainable fishing pressure is the alteration of trophic interactions that are particularly important in structuring coral reef ecosystems (Jackson *et al.*, 2012; Jackson *et al.*, 2014; Ruppert *et al.*, 2013). These trophic interactions include reducing population abundance of herbivorous fish species that control algal growth, limiting the size structure of fish populations, reducing species richness of herbivorous fish, and releasing corallivores from predator control. Thus, an important aspect of maintaining resilience in coral reef ecosystems is to sustain functional populations of herbivores, especially the larger parrotfish and other key functional herbivorous fish (Hughes *et al.*, 2010; Jackson *et al.*, 2012; Jackson *et al.*, 2014; Kennedy *et al.*, 2013). Further, Jackson *et al.* (2014) considers overfishing (associated with high human densities) to be one of the major causes of the region-wide decline in Caribbean corals while acknowledging that climate threats are likely to be major sources of mortality in the future. In addition to direct overfishing of primary consumers such as parrotfish, recent studies found that overfishing of top reef predators such as sharks and other predatory fish, such as large groupers in the Caribbean, can have an impact that cascades down the food chain, potentially contributing to mesopredator release, and ultimately altering the numbers of primary consumers available to control algal growth (Jackson *et al.*, 2012; Jackson *et al.*, 2014; Ruppert *et al.*, 2013).

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding the trophic effects of fishing remains unchanged from the proposed rule. Trophic effects of fishing are a medium importance threat in assessing global extinction risk for the 65 corals in this final rule. Because the main effect of trophic effects of reef

fishing is habitat alteration, there are no species-specific levels of exposure and susceptibility. However, the extent to which an individual species' recruitment is affected is discussed in more detail in the Species-specific Information and Determinations section, when species-specific information is available.

*Sedimentation (Low-Medium Importance Threat, ESA Factors A and E)*

Sedimentation is considered under ESA Factor A—the present or threatened destruction, modification, or curtailment of its habitat or range—and ESA Factor E—other natural or manmade factors affecting the continued existence of the species—because the effect of the threat, resulting from human activity, is both to limit the availability of habitat for corals and to directly impact individuals of coral species. In the proposed rule we described the threat of sedimentation as follows. Human activities in coastal and inland watersheds introduce sediment into the ocean by a variety of mechanisms, including river discharge, surface runoff, groundwater seeps, and atmospheric deposition. Humans also introduce sewage into coastal waters through direct discharge, treatment plants, and septic leakage. Elevated sediment levels are generated by poor land use practices and coastal and nearshore construction.

The most common direct effect of sedimentation is deposition of sediment on coral surfaces as sediment settles out from the water column. Corals with certain morphologies (*e.g.*, mounding) can passively reject settling sediments. In addition, corals can actively displace sediment by ciliary action or mucous production, both of which require energetic expenditures. Corals with large calices (skeletal component that holds the polyp) tend to be better at actively rejecting sediment. Some coral species can tolerate complete burial for several days. Corals that are unsuccessful in removing sediment will be smothered and die. Sediment can also induce sublethal effects, such as reductions in tissue thickness, polyp swelling, zooxanthellae loss, and excess mucus production. In addition, suspended sediment can reduce the amount of light in the water column, making less energy available for coral photosynthesis and growth. Sedimentation also impedes fertilization of spawned gametes and reduces larval settlement and survival of recruits and juveniles.

Although it is difficult to quantitatively predict the extinction risk

that sedimentation poses to the corals under consideration, human activity has resulted in quantifiable increases in sediment inputs in some reef areas. Continued increases in coastal human populations combined with poor land use and nearshore development practices will likely increase sediment delivery to reef systems. Nearshore sediment levels will also likely increase with sea-level rise. Greater inundation of reef flats can erode soil at the shoreline and resuspend lagoon deposits, producing greater sediment transport and potentially leading to leeward reefs being flooded with turbid lagoon waters or buried by off-bank sediment transport. Sediment stress and turbidity also can induce bleaching, although some corals may be more tolerant of elevated short-term levels of sedimentation.

Exposure to sedimentation can be moderated by distance of some coral habitats from areas where sedimentation is chronically or sporadically heavy, resulting in some habitats being unaffected or very lightly affected by sedimentation. Exposure to sedimentation for particular species may also be moderated by depth of habitats. Exposure to sedimentation is expected to increase as human activities that produce sedimentation expand over time.

Sedimentation is also likely to interact with many other threats, such as other land-based sources of pollution and warming-induced bleaching, especially considering that sedimentation is likely to increase across the ranges of many of the 65 species over the foreseeable future. For example, when coral communities that are chronically affected by sedimentation experience a warming-induced bleaching event, a disease outbreak, or a toxic spill, the consequences for those corals can be much more severe than in communities not affected by sedimentation.

Comment 25 underscored the importance of sedimentation as a considerable local threat to corals, and highlighted the potential of sedimentation to interact and potentially exacerbate other threats. A few commenters provided references (Bonkosky *et al.*, 2009; Hernández-Delgado *et al.*, 2012; Hernández-Delgado *et al.*, 2011) that discussed sedimentation as a threat to corals.

We also gathered supplemental studies on the threat of sedimentation since the proposed rule was published. Three points in particular from the proposed rule were affirmed by the supplemental studies. Sedimentation can have interactive effects with other

stressors including disease and climate factors such as bleaching susceptibility and reduced calcification (Atweberhan *et al.*, 2013; Suggett *et al.*, 2013). MPAs provide little protection against indirect stressors like sedimentation from upland activities (Halpern *et al.*, 2013). The effects of sedimentation can be variable for different coral species and may depend on other environmental conditions (Blakeway *et al.*, 2013; Suggett *et al.*, 2013).

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding sedimentation remains unchanged from the proposed rule. Sedimentation is a low to medium importance threat in assessing global extinction risk for the 65 corals in this final rule. The impact of sedimentation may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by sedimentation depends on its particular level of susceptibility combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is considered for each species in the Species-specific Information and Determinations section.

*Nutrients (Low-Medium Importance Threat, ESA Factors A and E)*

Nutrient enrichment is considered under ESA Factor A—the present or threatened destruction, modification, or curtailment of its habitat or range—and ESA Factor E—other natural or manmade factors affecting the continued existence of the species—because the effect of the threat, resulting from human activity, is both to limit the availability of habitat for corals and directly impact individuals of coral species. In the proposed rule we described the threat of nutrient over-enrichment as follows. Elevated nutrients affect corals through two main mechanisms: Direct impacts on coral physiology and indirect effects through nutrient-stimulation of other community components (*e.g.*, macroalgal turfs and seaweeds, and filter feeders) that compete with corals for space on the reef. Increased nutrients can decrease calcification; however, nutrients may also enhance linear extension, while reducing skeletal density. Either condition results in corals that are more prone to breakage or erosion, but individual species do have varying tolerances to increased nutrients. The main vectors of anthropogenic nutrients are point-source discharges (such as rivers or sewage outfalls) and surface runoff from modified watersheds. Natural processes,

such as *in situ* nitrogen fixation and delivery of nutrient-rich deep water by internal waves and upwelling also bring nutrients to coral reefs.

Exposure to nutrients can be moderated by distance of some coral habitats from areas where nutrients are chronically or sporadically heavy (e.g., heavily populated areas). However, nutrient over-enrichment can still result from sparsely populated areas; and these nutrients can be quickly transported large distances. Therefore, distance is less of a moderating factor for nutrients than for sedimentation. Similarly, although nutrient exposure may also be moderated by the depth of some habitats, nutrient impacts extend deeper than sedimentation impacts. Exposure to nutrients is expected to increase as human activities that produce nutrients expand over time.

Nutrients are likely to interact with many other threats, especially considering that nutrient over-enrichment is likely to increase across the ranges of many of the 65 corals over the foreseeable future. For example, when coral communities that are chronically affected by nutrients experience a warming-induced bleaching event, a disease outbreak, or a toxic spill, the consequences for corals can be much more severe than in communities not affected by nutrients.

Comment 26 supported and reiterated the effects nutrients can have on corals. Some of the individual commenters provided studies (Bonkosky *et al.*, 2009; Connolly *et al.*, 2012; Cuning and Baker, 2013; Fabricius *et al.*, 2013; Hernandez-Delgado *et al.*, 2011; Hernández-Delgado *et al.*, 2008; Méndez-Lázaro *et al.*, 2012; Wiedenmann *et al.*, 2013) to reinforce their support. Bonkosky *et al.* (2009) provided further evidence that elevated turbidity and nutrient enrichment from human waste discharge has an extensive impact on coral reef ecosystems. In response to contradictory results from other studies as to whether nutrients increase thermal stress or increase resistance to higher temperature for corals, Fabricius *et al.* (2013) exposed corals to both elevated nutrients and heat stress. They found higher mortality occurred in the elevated nutrient-heat stress treatments versus heat-stressed alone and controls. Wiedenmann *et al.* (2013) found that unfavorable ratios of dissolved inorganic nutrients in the water column led to phosphate starvation of symbiotic algae, reducing thermal tolerance. Cuning and Baker (2013) found higher nutrient loads can lead to higher densities of symbionts, and corals with higher densities of

symbionts were more susceptible to bleaching.

We also gathered supplemental information on how elevated nutrients interact with other threats, including coral bleaching and disease. One study tested the interactive effects of nutrient loading with both bleaching and disease and found that coral disease prevalence and severity as well as coral bleaching were increased in nutrient enriched plots (Vega Thurber *et al.*, 2013). Ateweberhan *et al.* (2013) note that most studies on the subject of nutrient enrichment and high temperatures also present evidence of negative effects on calcification due to higher nutrient levels, although both positive and negative effects have been reported. Nutrient enrichment can also interact with the threat of coral disease by encouraging the proliferation of disease-causing microorganisms and bioeroders, such as boring sponges, and intensifying the growth of fleshy macroalgae that harbor and spread coral diseases (Ateweberhan *et al.*, 2013; Vega Thurber *et al.*, 2013).

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding nutrient over-enrichment remains unchanged from the proposed rule. Nutrients are a low to medium importance threat in assessing global extinction risk for the 65 corals in this final rule. The impact of elevated nutrients may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by nutrient enrichment depends on its particular level of susceptibility, combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is considered for each species in the Species-specific Information and Determinations section.

#### *Sea-Level Rise (Low-Medium Threat, ESA Factor A)*

Sea-level rise is considered under ESA Factor A—the present or threatened destruction, modification, or curtailment of its habitat or range—because the effect of the threat is to the availability of corals' habitat and not directly to the species themselves. In the proposed rule we described the threat of sea-level rise as follows. The effects of sea-level rise may act on various coral life history events, including larval settlement, polyp development, and juvenile growth, and can contribute to adult mortality and colony fragmentation, mostly due to increased sedimentation and decreased water quality (reduced light availability)

caused by coastal inundation. The best available information suggests that sea level will continue to rise due to thermal expansion and the melting of land and sea ice. Theoretically, any rise in sea-level could potentially provide additional habitat for corals living near the sea surface. Many corals that inhabit the relatively narrow zone near the ocean surface have rapid growth rates when healthy, which allowed them to keep up with sea-level rise during the past periods of rapid climate change associated with deglaciation and warming. However, depending on the rate and amount of sea-level rise, rapid rises can lead to reef drowning. Rapid rises in sea level could affect many of the proposed coral species by both submerging them below their common depth range and, more likely, by degrading water quality through coastal erosion and potentially severe sedimentation or enlargement of lagoons and shelf areas. Rising sea level is likely to cause mixed responses in the 65 corals depending on their depth preferences, sedimentation tolerances, growth rates, and the nearshore topography. Reductions in growth rate due to local stressors, bleaching, infectious disease, and ocean acidification may prevent the species from keeping up with sea-level rise (i.e., from growing at a rate that will allow them to continue to occupy their preferred depth range despite sea-level rise).

The rate and amount of future sea-level rise remains uncertain. Until the past few years, sea-level rise was predicted to be in the range of only about one half meter by 2100. However, more recent estimated rates are higher, based upon evidence that the Greenland and Antarctic ice sheets are much more vulnerable than previously thought. While there is large variability in predictions of sea-level rise, AR4 likely underestimated the rates under all scenarios.

Fast-growing branching corals were able to keep up with the first 3 m of sea-level rise during the warming that led to the last interglacial period. However, whether the 65 corals in this final rule will be able to survive 3 m or more of future sea-level rise will depend on whether growth rates are reduced as a result of other risk factors, such as local environmental stressors, bleaching, infectious disease, and ocean acidification. Additionally, lack of suitable new habitat, limited success in sexual recruitment, coastal runoff, and coastal hardening will compound some corals' ability to survive rapid sea-level rise.

This threat is expected to disproportionately affect shallow areas adjacent to degraded coastlines, as ocean inundation results in higher levels of sedimentation from the newly-inundated coastlines to the shallow areas. Exposure to sea-level rise will be moderated by horizontal and vertical distances of reef-building coral habitats from inundated, degraded coastlines. Exposure to sea-level rise will increase over time as the rate of rise increases.

Sea-level rise is likely to interact with other threats, especially considering that sea-level rise is likely to increase across the ranges of the 65 corals over the foreseeable future. In particular, the inundation of developed areas (e.g., urban and agricultural areas) and other areas where shoreline sediments are easily eroded by sea-level rise is likely to degrade water quality of adjacent coral habitat through increased sediment and nutrient runoff and the potential release of toxic contamination.

Comment 27 supported the Consensus Statement on Climate Change and Coral Reefs, which specifies that sea-levels have already risen and that future rising sea-levels will be accompanied by increased sedimentation levels. We received no additional supplemental information on this threat.

We also gathered supplemental information to update the analysis presented in the proposed rule. In the proposed rule, we noted that AR4 likely underestimated rates of projected sea-level rise. AR5's WGI represents a substantial advance from AR4. The first section of WGI considers observations of climate system change, which refers to descriptions of past climate patterns. WGI concludes it is virtually certain that the global mean sea level rose by 19 cm from 1901 to 2010. The anthropogenic ocean warming observed since the 1970s has contributed to global sea-level rise over this period through ice melting and thermal expansion. Projections for future sea-level-rise in RCP8.5 for the period 2081 to 2100 are 0.53 to 0.97 meter higher than the period 1986 to 2005. In addition, WGI concluded that it is virtually certain that global mean sea-level rise will continue beyond 2100. WGI also reported that it is very likely that in the twenty-first century and beyond, sea-level change will have a strong regional pattern (IPCC, 2013).

After considering this supplemental information in addition to that which was previously available, our conclusion regarding sea-level rise remains unchanged from the proposed rule. Sea-level rise is a low to medium importance threat in assessing global extinction risk for the 65 corals in this

final rule. The impact of sea-level-rise may be mediated by some factors and the extent to which the extinction risk of a coral species is impacted by sea-level-rise depends on its particular level of susceptibility, combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is considered for each species in the Species-specific Information and Determinations section.

#### *Predation (Low Threat, ESA Factor C)*

Predation is considered under ESA Factor C—disease or predation. In the proposed rule we described the threat of predation as follows. Predation on some coral genera by many corallivorous species of fish and invertebrates (e.g., snails and seastars) is a chronic, though occasionally acute, energy drain. It is a threat that has been identified for most coral life stages. Thus, predation factored into the extinction risk analysis for each of the 65 corals. Numerous studies have documented the quantitative impact of predation by various taxa on coral tissue and skeleton. Predators can indirectly affect the distribution of corals by preferentially consuming faster-growing coral species, thus allowing slower-growing corals to compete for space on the reef. The most notable example of predation impacts in the Indo-Pacific are from large aggregations or outbreaks of crown-of-thorns seastar. The specific cause of crown-of-thorns seastar outbreaks is unknown. Crown-of-thorns seastar can reduce living coral cover to less than one percent during outbreaks, changing coral community structure, promoting algal colonization, and affecting fish population dynamics.

Exposure to predation by corallivores is moderated by presence of predators of the corallivores. For example, corallivorous reef fish prey on corals, and piscivorous reef fish and sharks prey on the corallivores; thus, high abundances of piscivorous reef fish and sharks moderate coral predation. Abundances of piscivorous reef fish and sharks vary spatially because of different ecological conditions and human exploitation levels. Exposure to predation is also moderated by distance from physical conditions that allow corallivore populations to grow. For example, in the Indo-Pacific, high nutrient runoff from continents and high islands improves reproductive conditions for crown-of-thorns seastar, thus coral predation by crown-of-thorns seastar is moderated by distance from such conditions. Predation can also be moderated by depth of many habitats because abundances of many

corallivorous species decline with depth. Exposure to predation can increase over time as conditions change, but may be moderated by distance and depth for certain species, which depends upon the distribution and abundances of the species.

Predation of coral colonies can increase the likelihood of the colonies being infected by disease, and likewise diseased colonies may be more likely to be preyed upon. There are likely other examples of cumulative and interactive effects of predation with other threats to corals.

Comment 28 suggested predation and exposure values for some individual species, but did not provide supplemental information on the threat. We also gathered supplemental information that supports and reiterates the analysis presented in the proposed rule. Bonaldo *et al.* (2011) documented spatial and temporal variation in coral predation by parrotfishes on the Great Barrier Reef. Lenihan *et al.* (2011) assessed the degree to which the performance of recently recruited branching corals was influenced by several factors, including corallivory. They found that partial predation by corallivorous fishes is an important but habitat-modulated constraint for branching corals and, overall, corallivory had variable effects on corals of different genera. Last, De'ath *et al.* (2012) documented that 42 percent of the decline in coral cover on the GBR is attributable to crown-of-thorns seastar predation.

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding predation remains unchanged from the proposed rule. Predation is a low importance threat in assessing global extinction risk for the 65 corals in this final rule. The impact of predation may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by predation depends on its particular level of susceptibility combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is considered for each species in the Species-specific Information and Determinations section.

#### *Collection and Trade (Low Threat, ESA Factor B)*

Collection and trade is considered under ESA Factor B—overutilization for commercial, recreational, scientific, or educational purposes. In the proposed rule, we described the threat of collection and trade as follows.

Globally, 1.5 million live stony coral colonies are reported to be collected from at least 45 countries each year, with the United States consuming the largest portion of live corals (64 percent) and live rock (95 percent) for the aquarium trade. The imports of live corals taken directly from coral reefs (not from aquaculture) increased by 600 percent between 1988 and 2007, while the global trade in live coral increased by nearly 1,500 percent. Harvest of stony corals is usually highly destructive, and results in removing and discarding large amounts of live coral that go unsold and damaging reef habitats around live corals. While collection is a highly spatially-focused impact, it can result in significant impacts and was considered to contribute to individual species' extinction risk. However, we ultimately ranked this threat as low overall because of species-specific factors (*i.e.*, some species are preferentially affected) as well as distance and depth factors that create barriers to human access.

As described in Comments 29 and 30, we received a significant amount of supplemental information via public comments and gathered supplemental information on three aspects of the threat of collection and trade on reef-building corals and coral reef ecosystems: (1) Wild collection of corals, including information about the physical and ecological impacts of wild collection of coral colonies and/or fragments from their natural habitats; (2) captive culture including information regarding the development of mariculture and aquaculture operations, as well as the role of home aquaria as they relate to trade, including all commercial, recreational, and educational coral-raising operations in marine environments as well as in captivity; and (3) the global marine ornamental trade industry, including detailed information regarding trade of both live and dead corals and other coral reef wildlife.

For the purposes of this final rule, collection and trade refers to the physical process of taking corals from their natural habitat on coral reefs for the purpose of sale in the ornamental trade industry. We define wild collection as the physical removal or capture of coral colonies, fragments, and polyps from their natural habitat. This section also discusses the use of captive breeding techniques via aquaculture and mariculture for the purposes of trade. Captive culture techniques are increasingly used to supply the aquarium trade industry and potentially reduce the amount of corals collected from the wild to meet demand

(Thornhill, 2012; Wood *et al.*, 2012). We define aquaculture as the land-based ('*ex situ*') propagation or grow out of corals. Examples of this include corals grown in home aquaria or terrestrial coral farms. We define mariculture as the ocean-based ('*in situ*') propagation or grow out of corals. Examples of this include corals grown in coral farms and nursery areas in marine environments. The phrase "captive culture" is used interchangeably to refer to captive breeding of corals, both via aquaculture or mariculture techniques.

The ecological and socio-economic impacts of the ornamental trade industry for corals are numerous, and can include overharvesting, collateral damage to coral reef habitat, and potential introduction of exotic species (Rhyne *et al.*, 2012). Wild collection of stony corals is usually highly destructive, resulting in removing and discarding large amounts of live coral that often go unsold for various reasons. Additionally, collection techniques can be physically damaging to reef habitat around live corals. In a recent, thorough review of ecological impacts and practices of the coral reef wildlife trade, Thornhill (2012) identifies and describes five overarching potential impacts: (1) Effects on target population such as over-exploitation and local population extirpations; (2) habitat impacts such as reduced coral cover, diversity, and rugosity; (3) effects on associated species such as decreased abundance, biomass, and diversity of reef fish, invertebrates, and other species due to loss or destruction of habitat; (4) ecosystem impacts such as increased degradation and erosion leading to reduced resilience; and (5) socio-economic impacts such as user group conflict between tourists, fishers, *etc.*

Collection and trade of coral colonies can also increase the likelihood of the colonies being infected by disease, as a result of both the directed and incidental breakage of colonies, which are then more easily infected (Brainard *et al.*, 2011). Further, destructive practices for collection of other coral reef wildlife, such as the use of cyanide for capturing reef fish, can also have deleterious effects on coral reef habitat in general. Currently, cyanide fishing is practiced in 15 countries, many of which are major marine wildlife trade exporters (Thornhill, 2012). There are likely many other examples of cumulative and interactive effects of collection and trade that pose a threat to corals. Given the paucity of data for the coral reef wildlife trade, it is difficult to accurately estimate mortality rates

directly resulting from collection practices (Thornhill, 2012).

The rapid increase of coral reef species entering markets in the United States and Europe and the sustainability of the aquarium trade in terms of driving collection of wild specimens have been of great concern to governments, scientists, conservationists, and conscientious aquarium hobbyists alike (Olivotto *et al.*, 2011; Rhyne and Tlusty, 2012). However, production of marine wildlife for home aquaria (*i.e.*, the aquarium hobbyist trade) through captive culture is an increasingly growing sector of the ornamental trade industry. Recently, advances in both aquaculture and mariculture propagation techniques show promise in shifting the demand of the ornamental trade industry away from wild-collected corals to corals reared via captive-culture techniques. Such techniques are possible since many corals, especially fast-growing branching corals, are capable of asexual reproduction via a process known as fragmentation or "fragging" (Brainard *et al.*, 2011; Rhyne *et al.*, 2012). According to CITES import and export reports, maricultured corals accounted for approximately 20 percent of total live trade in 2010 (Wood *et al.* 2012), but other studies suggest that captive-cultured corals account for only 2 percent of the live coral trade (Thornhill, 2012).

Globally, there are approximately two million aquarium hobbyists involved in a complex trade network that sells an estimated 50 million corals every year to use (Rhyne *et al.*, 2012). According to the Florida Department of Agriculture and Consumer Services, there are 87 certified aquaculture facilities listing corals as a product in Florida alone. The study hypothesized that a notable decline in U.S. imports of corals occurred after 2006 as a result of increased domestic coral production as well as the global economic downturn. Import reports do not account for this "hidden" domestic production, and statistical tracking of this type of coral production is lacking (Rhyne *et al.*, 2012). In addition to increasing domestic production of corals, some major source countries such as Indonesia are increasing production via mariculture activities to reduce wild collection pressure on coral reefs, and supporting coral farming as a potential alternative to fishing for reef fish and collection of wild corals (Pomeroy *et al.*, 2006). For example, according to 2009 U.S. import reports, 26 percent of *Acropora* species were identified under CITES codes which indicated that these colonies were produced via captive-

culture techniques (Rhyne *et al.*, 2012). However, since CITES codes are self-determined by exporter countries, there may be some inconsistencies in how those codes are applied (Wood *et al.*, 2012). As of 2008, there were 55 coral farms scattered throughout the different provinces of Indonesia (Timotius *et al.*, 2009); however, this number may be increasing since Indonesia's government has mandated companies and traders involved in the coral trade to utilize captive culture techniques in hopes of eventually phasing out wild collection of corals.

There are a number of challenges associated with developing aquaculture or mariculture operations for coral species, including technical capacity and know-how, high capital investments and operating costs, and high levels of production risk (Ferse *et al.*, 2012; Pomeroy *et al.*, 2006). Culturing corals has not been an easy task, predominantly due to the lack of knowledge regarding reproductive and larval biology for most traded species (Olivotto *et al.*, 2011). Further, most mariculture operations tend to focus predominantly on fast-growing corals, while successful propagation techniques for the popular slow-growing, large-polyp species have not yet been developed (Wood *et al.*, 2012). There is also the increasingly popular trend of using ocean-based coral nurseries for the purposes of propagating coral fragments to a suitable size and subsequently out-planting those coral fragments on degraded reefs to aid in reef restoration efforts. These types of activities are also considered in the Conservation Efforts section of the rule.

The export of marine organisms for the ornamental trade industry is a global industry. As described in the proposed rule, it is estimated that 1.5 million live stony coral colonies are collected from at least 45 countries each year, with an estimated 11 to 12 million coral pieces (*i.e.*, fragments from larger colonies) traded every year (Brainard *et al.*, 2011; Wabnitz, 2003). In addition to live stony corals, approximately 13 to 40 million reef fish, four million pounds of dead coral skeleton, and nine to 10 million other invertebrates are extracted from coral reef ecosystems across the world (Thornhill, 2012). For corals, trade can be broken down into several categories, including: Coral rock (*i.e.*, rock and substrate that may have live settled coral polyps among other marine organisms), live wild coral, live maricultured coral, and dead coral skeleton. Yet, numbers of corals traded in these categories are very difficult to accurately estimate for a variety of reasons. First, corals are colonial, vary

in size, and can be fragmented into many smaller pieces. Additionally, reporting of trade volume is inconsistent and varies between reporting pieces and weight, and live rock and corals are often confused with each other and misreported (Thornhill, 2012). Currently, Indonesia is the primary source country of live corals; it exports approximately one million corals annually and represents an estimated 91 percent of the global supply market as of 2005 (Bruckner and Borneman, 2006; Thornhill, 2012; Timotius *et al.*, 2009). Other major exporters of scleractinian corals include Fiji, Solomon Islands, Tonga, and Australia. The largest importers of coral reef wildlife include the United States, European Union, and Japan. The United States accounted for an average of 61 percent of global imports from 2000–2010 (Wood *et al.*, 2012). Imports of live corals into the United States taken directly from coral reefs (not from aquacultured or maricultured sources) increased by 600 percent between 1988 and 2007, while the global imports of live coral increased by nearly 1,500 percent (Brainard *et al.*, 2011; Thornhill, 2012; Tissot *et al.*, 2010). Import and export data shows overall increasing trends for trade of live coral pieces between 2000–2009, with a slight dip in 2010 (Wood *et al.*, 2012). In addition, undocumented, illegal live coral trade is estimated to represent approximately 25 percent of the legal trade level, although these numbers are difficult to estimate considering the secretive nature of the illegal trade (Jones, 2008; Thornhill, 2012).

The international coral trade was established by 1950 and was dominated by the Philippines until 1977 when a national ban on wild collection and export was introduced (Wood *et al.*, 2012). It was then that Indonesia surpassed the Philippines to provide the majority of corals to the market. In the 1980s and 1990s, the international coral trade still focused on the trade of dead coral skeletons for home décor and curios. In recent years, the focus has shifted to live corals for the marine reef aquarium trade due to increased interest in home aquaria and advances in coral husbandry in North America and Europe, as well as the advent of modern air cargo methods (Rhyne *et al.*, 2012; Thornhill, 2012; Wood *et al.*, 2012). As stated previously, there is a complex global trade network of approximately two million aquarium hobbyists that sells upwards of 50 million coral reef animals every year (Rhyne *et al.*, 2012). Collection of corals for display in public aquaria for educational purposes

represents a small portion of the coral reef wildlife trade, and public aquaria likely produce as many corals as they consume by using captive-culture techniques (Thornhill, 2012).

There has been some significant progress in captive culture of coral species using aquaculture and/or mariculture for the purposes of trade. Still, commercial-scale production of most species currently suffers several technical bottlenecks, including the long and often arduous supply chain from ocean to aquarium (*e.g.*, capture, collection, handling, and transport), which often results in mortality ranging from a few percent up to 80 percent. For example, in an analysis of confiscated coral shipments, a majority of the corals were found in poor condition. On the way to their final destination, coral colonies may experience significant temperature drops in the shipping water, poor water quality, and physical damage from repeated handling of the shipping boxes and bags resulting in mortality of a large proportion of colonies through subsequent bacterial infections (Jones, 2008). These non-reported rates of biomass loss may significantly underestimate the ecological impacts of the trade as more corals are collected to make up the losses (Cohen *et al.*, 2013; Thornhill, 2012). Distinguishing between specimens collected under regulated conditions from those collected using illegal or destructive fishing practices is very difficult (Cohen *et al.*, 2013; Wabnitz, 2003).

Traceability and tracking of cultured corals versus wild-collected corals is extremely difficult as there is no morphological or biological difference between them, making distinction almost impossible (Olivotto *et al.*, 2011). For example, a coral can be broken into fragments and labeled as cultured, when in fact it was collected from the wild. There is some evidence to suggest that culture of live corals has the potential to affect trends in the trade industry by reducing wild collection and provide an economically and financially feasible alternative livelihood for local communities in the Indo-Pacific. Even so, coral mariculture development in the Indo-Pacific is still in its infancy and requires a number of conditions to be met in order for these operations to be commercially profitable, sustainable, and traceable (Cohen *et al.*, 2013; Pomeroy *et al.*, 2006). It is also important to note that not all species lend themselves to culture. In fact, only a small number of coral genera have the ability to be commercially cultured (Rhyne *et al.*, 2012). According to some sources, approximately 98 percent of

live corals in the ornamental trade are still collected from the wild, with only 2 percent originating from captive bred sources such as coral farms and nurseries (Ferse *et al.*, 2012; Thornhill, 2012), but, according to a different analysis of import reports between 2000 and 2010, captive cultured corals made up approximately 20 percent of total imports, and these originated almost entirely from Indonesia (Wood *et al.*, 2012). Therefore, there are still significant data deficiencies and a large amount of uncertainty as to how much of an impact captive cultured corals are having on the ornamental trade.

Significant supplemental information was received in public comments on the proposed rule or otherwise gathered on collection and trade of coral species. As previously described in the SRR and proposed rule, there are numerous ecological impacts from the physical process of removing corals and other wildlife from the reef. Trade practices that rely on the collection of wild individuals may damage or destroy adult and juvenile reef corals. Additionally, removal of reef fish and other organisms for trade purposes may also result in ecological impacts to reef ecosystems (Brainard *et al.*, 2011). The ten most popular coral genera involved in the ornamental trade by volume are: *Acropora* (Indo-Pacific only), *Euphyllia*, *Goniopora*, *Trachyphyllia*, *Plerogyra*, *Montipora*, *Heliofungia*, *Lobophyllia*, *Porites*, and *Turbinaria* (Jones, 2008; Thornhill, 2012), all of which represent 31 of the coral species considered in this final rule. *Acropora* species are in the highest demand followed by the large polyp species such as *Euphyllia* (Jones, 2008). Culturing corals through aquaculture and/or mariculture techniques is becoming an increasingly popular tool to help move the aquarium trade away from collection of wild corals. Still, these techniques are fairly new and in need of many improvements before being considered a viable solution in shifting market demand from wild-collected to captive cultured corals. As it currently stands, the amount of unreported, illegal, and unregulated collection, combined with the large amount of biomass loss along the supply chain raises serious questions as to the sustainability of the ornamental trade (Cohen *et al.*, 2013). Overall, collection and trade of coral reef wildlife is considered to contribute to some individual species' extinction risk.

In our previous analysis, collection and trade were generally considered to be a threat to coral reefs, as well as particular individual coral species, but extinction risk as a result of collection

and trade activities for the 65 corals proposed for ESA listing was considered to be "low" (Brainard *et al.*, 2011). After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding the threat of collection and trade remains unchanged from the proposed rule. Collection and trade is a low importance threat in assessing global extinction risk for the 65 corals in this final rule, and even less so for the seven Caribbean species due to undesirable appearance and growth characteristics for trade. The impact of collection and trade may be mediated by several factors and the extent to which the extinction risk of a coral species is impacted by collection and trade depends on its particular level of susceptibility, combined with its spatial and demographic characteristics in the context of worsening environmental conditions out to 2100, which is considered for each species in the Species Information and Determinations section. Information regarding the adequacy of regulations related to the marine ornamental trade such as CITES and other laws can be found in the Local Regulatory Mechanisms section of the Final Management Report (NMFS, 2012b). Additionally, coral restoration projects using ocean-based, nursery-reared corals are also becoming increasingly popular as a complement to existing management tools. Information related to the roles that coral farms, coral nurseries, and aquaria (both public and private) play in coral reef conservation is discussed in the Conservation Efforts sub-section of the rule.

#### *Inadequacy of Existing Regulatory Mechanisms (ESA Factor D)*

Regulatory mechanisms are considered under Factor D—Inadequacy of Existing Regulatory Mechanisms. As previously described in the proposed rule, we developed a Draft Management Report to assess the contribution of "inadequacy of regulatory mechanisms" to the extinction risk of corals. The Draft Management Report identified: (1) Existing regulatory mechanisms relevant to threats to the 82 candidate coral species; and (2) conservation efforts with regard to the status of the 82 candidate coral species. This Draft was peer reviewed and released with the SRR in April 2012, with a request for any information that we may have omitted. We incorporated all of the information we received into the Final Management Report, which formed the basis of our evaluation of this factor's effect on the extinction risk of the 82

candidate coral species in the proposed rule.

The Final Management Report identified existing regulatory mechanisms that were relevant to the threats to coral species. It was organized in two sections: (1) Existing regulatory mechanisms that are relevant to addressing global-scale threats to addressing other threats to corals. The proposed rule summarized the information from that report as follows.

Greenhouse gas emissions are regulated through multi-state agreements, at the international level, and through statutes and regulations, at the national, state, or provincial level. One of the key international agreements relevant to attempts to control GHG emissions, the Copenhagen Accord, was developed in 2009 by the Conference of Parties to the United Nations Framework Convention on Climate Change. The Copenhagen Accord identifies specific information provided by Parties on quantified economy-wide emissions targets for 2020 and on nationally appropriate mitigation actions to the goal of capping increasing average global temperature at 2 °C above pre-industrial levels. Overall, the proposed rule concluded that existing regulatory mechanisms with the objective of reducing GHG emissions were inadequate to prevent the impacts to corals and coral reefs from ocean warming, ocean acidification, and other climate change-related threats. After an in-depth analysis of international agreements to curb GHG emissions and their respective progress, it appeared unlikely that Parties would be able to collectively achieve, in the near term, climate change avoidance goals outlined via international agreements.

Additionally, none of the major global initiatives appeared to be ambitious enough, even if all terms were met, to reduce GHG emissions to the level necessary to minimize impacts to coral reefs and prevent what are predicted to be severe consequences for corals worldwide. The evidence suggested that existing regulatory mechanisms at the global scale in the form of international agreements to reduce GHG emissions were insufficient to prevent widespread impacts to corals.

Existing regulatory mechanisms directly or indirectly addressing the localized threats identified in the proposed rule (*i.e.*, those threats not related to GHGs and global climate change) are primarily national and local fisheries, coastal, and watershed management laws and regulations in the 84 countries within the collective ranges of the 82 coral species. Because of the large number of threats, and the

immense number of regulatory mechanisms in the 84 countries, we concluded in the proposed rule that a regulation-by-regulation assessment of adequacy was not possible. Furthermore, with the exception of *Acropora palmata* and *A. cervicornis* in the Caribbean, there was not enough information available to determine the effects of specific regulatory mechanisms on individual coral species, given the lack of information on specific locations of individual species (the adequacy of existing local regulatory mechanisms relevant to threats impacting the Caribbean acroporids was evaluated in detail in those species' 2005 status review, and that information is incorporated into this rule's final findings for those species). However, general patterns included: (1) Fisheries management regimes regulate reef fishing in many parts of the collective ranges of the proposed coral species, albeit at varying levels of success; (2) laws addressing land-based sources of pollution are less effective than those regulating fisheries; (3) coral reef and coastal marine protected areas have increased several-fold in the last decade, reducing some threats through regulation or banning of fishing, coastal development, and other activities contributing to localized threats; and (4) the most effective regulatory mechanisms address the threats other than climate change. We generally concluded that because the local threats have impacted and continue to impact corals across their ranges, collectively, the existing regulations were not preventing or controlling local threats. Further, there was insufficient information to determine if an individual species was impacted by inadequacy of individual existing regulations.

We received public comments and supplemental information on the inadequacy of existing regulatory mechanisms. As a result, we incorporated any information we received into this final rule, which supplemented the basis for our final analysis and determination of the inadequacy of existing regulatory mechanisms in each species determination.

Comments 31–33 provided supplemental information, which we incorporated into this final rule. Specifically, we received information on how local management actions potentially confer resilience benefits to coral reef ecosystems. The public comments and supplemental information on the inadequacy of existing regulatory mechanisms are discussed below in three sections: (1)

Updates to adequacy of global regulatory mechanisms; (2) updates to adequacy of local regulatory mechanisms; and (3) local management as it applies to reef resilience.

Since the release of the Final Management Report, there have been two additional conferences of the Parties to the United Nations Framework Convention on Climate Change. In 2012, the Parties met in Doha, Qatar, and they met again in Warsaw, Poland in 2013. The resulting decisions from both meetings were primarily to continue ongoing efforts to reach a new agreement for emissions reductions to be adopted at the 2015 meeting in Paris, and to have those implemented by 2020. The new agreement would maintain the same overall goal as the Copenhagen Accord, to cap additional warming at 2 °C. Within the United States, President Barack Obama released the President's Climate Action Plan in June 2013. The plan is three-pronged, including proposed actions for mitigation, adaptation, and international leadership. The actions listed for mitigation include completing carbon pollution standards for new and existing power plants, accelerating clean energy permitting, increasing funding for clean energy innovation and technology, increasing fuel economy standards, increasing energy efficiency in homes businesses and factories, and reducing other GHG emissions including hydrofluorocarbons and methane. The plan states that the United States is still committed to reducing GHG emissions 17 percent below 2005 levels by 2020 if all other major economies agree to similar reductions. Additional efforts made domestically related to climate change are more focused on facilitating adaptation to the impending changes to the environment due to climate change in order to maintain the country's natural and economic resources, but do not directly address the emission of GHGs.

As described in the proposed rule, existing regulatory mechanisms directly or indirectly addressing all of the localized threats identified in the SRR (*i.e.*, those threats not related to GHGs and global climate change) are primarily national and local fisheries, coastal, and watershed management laws and regulations in the 84 countries within the collective ranges of the 65 coral species. This final rule incorporates any information we received via public comment regarding recent local regulatory mechanisms or local regulatory mechanisms that were either previously mischaracterized or inadvertently omitted. This includes

some additions of various local laws as well as supplemental information regarding regulations pertaining to collection and trade of coral species. In addition, to better capture the breadth and scope of existing regulatory mechanisms on a species-by-species basis, we evaluated the presence and scope of five different categories of regulatory mechanisms in each of the 84 countries throughout the ranges of the 65 corals in this final rule. These categories of laws include: General protection of corals, reef fishing, marine protected areas, wild collection, and pollution.

For each coral species, we considered the relevant national laws, regulations, and other similar mechanisms that may reduce any of the threats described in our threat analyses for all countries in which the coral species has confirmed records of occurrence. To find each country where our 65 coral species have confirmed occurrence we used Veron's updated report on the listed coral species and their occurrence in various ecoregions (Veron, 2014). In considering countries' regulatory mechanisms, we give strongest weight to statutes and their implementing regulations and to management direction that stems from those laws and regulations.

In analyzing local regulatory mechanisms available for each coral species, five general categories emerged: General coral protection, coral collection control, fishing controls, pollution controls, and managed areas. General coral protection regulatory mechanisms include overarching environmental laws that may protect corals from damage, harm, and destruction, and specific coral reef management laws. In some instances, these general coral protection regulatory mechanisms are limited in scope because they apply only to certain areas or only regulate coral reef damage and do not prohibit it completely.

Coral collection regulatory mechanisms include specific laws that prohibit the collection, harvest, and mining of corals. In some instances, these coral collection regulatory mechanisms are limited in scope because they apply only to certain areas or are regulated but not prohibited.

Pollution control regulatory mechanisms include oil pollution laws, marine pollution laws, ship-based pollution laws, and coastal land use and development laws. In some instances, pollution regulatory mechanisms are limited in scope because they apply only to certain areas or to specific sources of pollution.

Fishing regulatory mechanisms include fisheries regulations that pertain

to reefs or regulations that prohibit explosives, poisons and chemicals, electrocution, spearfishing, specific mesh sizes of nets, or other fishing gear. In some instances, fishing regulatory mechanisms are limited in scope because they apply only to certain areas, or not all reef-damaging fishing methods are prohibited, or reef-damaging fishing methods are regulated but not prohibited.

Managed area regulatory mechanisms include the capacity to create national parks and reserves, sanctuaries, and marine protected areas. In some instances, managed area regulatory mechanisms are limited in scope, primarily because the managed area provides limited protection for coral reefs, only small percentages of the countries' coral reefs are protected within the managed areas, or the managed areas are not well administered.

The management results for each species can be found in the Species-Specific Information and Determination section of this rule. It should be noted that while some of these regulatory mechanisms were categorized as "limited in scope," it does not necessarily mean they are inadequate under ESA section 4(a)(1) Factor D.

We received a significant amount of information regarding the role of local management actions in building resilience into reef ecosystems. This section describes the emerging body of literature regarding the concept of reef resilience, defined as an ecosystem's capacity to absorb recurrent shocks or disturbances and adapt to change without compromising its ecological function or structural integrity. Until recently, the main drivers of coral reef decline included overfishing of herbivorous fish and nutrient loading from agriculture and other land-based sources of pollution. These stressors caused widespread changes in reef ecosystems over the past couple of centuries, and ultimately led to ecological shifts from coral-dominated systems to systems overrun by fleshy algae. These localized disturbances are now being compounded by climate change related threats, including increasingly frequent coral bleaching events as a result of ocean warming.

Many factors contribute to coral reef ecosystem resilience, including ecosystem condition, biological diversity, connectivity between areas, and local environmental conditions (Marshall and Schuttenberg, 2006; Obura, 2005). Implementing local actions that either protect or strengthen these resilience-conferring factors has the potential to help coral reef

ecosystems survive predicted increases in the frequency, duration, and severity of mass coral bleaching events (Obura, 2005) and may help reduce the extinction risk of some individual coral species.

In terms of local management actions, many acute disturbances such as coral bleaching are out of the direct control of reef managers and cannot be mitigated directly. Actions that can be taken to build reef resilience and enhance reef recovery include reducing physical disturbance and injury as a result of recreational activities, managing local watersheds and coastal areas to prevent sedimentation and nutrient run-off, and reducing fishing pressures on important herbivorous fish (Jackson *et al.*, 2014; Kennedy *et al.*, 2013; Marshall and Schuttenberg, 2006; Mumby and Steneck, 2011). For example, a recent study shows that eutrophication can increase thermal stress on inshore reef communities and management actions to reduce coastal eutrophication can improve the resistance and resilience of vulnerable coastal coral reefs to ocean warming (Fabricius *et al.*, 2013). Additionally, herbivorous fish play a crucial role in the recovery of coral reefs after major disturbance events. Severe warming and increases in ocean acidification alone can reduce resilience of coral reef ecosystems, particularly if those systems are already subject to overfishing of the key functional groups of herbivorous reef fishes and nutrient loading (Anthony *et al.*, 2011; Bellwood *et al.*, 2004). Elevated populations of herbivores have the potential to confer resilience benefits by encouraging greater niche diversification and creating functional redundancy. For example, it has been demonstrated that two complementary herbivore species were more successful at controlling algal blooms than a single species on its own, and management of herbivorous fish can help in reef regeneration after episodes of bleaching or disease that are impossible to locally regulate (Bellwood *et al.*, 2004; Burkepile and Hay, 2008; Roff and Mumby, 2012). Conversely, even unexploited populations of herbivorous fishes do not guarantee reef resilience; therefore, some reefs could lose resilience even under relatively low fishing pressure (Cheal *et al.*, 2010). Therefore, the entire suite of local threats and disturbances should be minimized through local management actions to ensure that reef resilience and recovery are also maximized. Establishing MPA networks is generally accepted as one of the more common management tools to help reduce impacts to coral reefs and build

resilience (Burke *et al.*, 2011; Keller *et al.*, 2009).

In a 2013 global review of 10,280 MPAs, it was found that approximately 2.93 percent of the world's oceans have MPA coverage; however, coverage does not necessarily equate to protection. Marine protected areas have often failed to prevent ongoing local threats such as overfishing due to management and/or design failure, as well as lack of local support, poor compliance, and inadequate resources to promote educational awareness and enforcement (Hughes *et al.*, 2007; Hughes *et al.*, 2010; Spalding *et al.*, 2013). A study by the World Resources Institute found that only 6 percent of the world's reefs occur in effectively managed MPAs (Burke *et al.*, 2011). Further, scientists are just beginning to understand spatial patterns of coral responses to disturbance. Efforts to identify coral reef areas with the greatest resilience are crucial for siting MPAs. This information has the potential to assist in future MPA design and management so that resistant patches of coral reef can be protected to ensure continued connectivity and subsequent recovery of nearby reefs that are less resistant. These strategies of tailoring management efforts across the marine environment depending on various responses to disturbance are still in their infancy, but it may eventually prove essential in adaptive management of reef resources in the face of future climate change-related disturbances (Mumby and Steneck, 2011). For these reasons, while MPAs are an important tool in response to the global degradation of coral reefs, they should not be considered a panacea (Hughes *et al.*, 2007).

In general, recent evidence suggests that management of local scale disturbances is essential to maintaining an adequate coral population density for successful reproduction and maintenance of genetic diversity and is therefore crucial to maintaining complex, bio-diverse coral reef ecosystems, given the predicted widespread impacts of climate change related threats (*e.g.*, Anthony *et al.*, 2011). The presence of effective local laws and regulations has the potential to help reduce impacts to coral reefs from threats on an ecosystem level, potentially extending the timeframe at which individual coral species may be in danger of extinction by providing a protective temporal buffer (*i.e.*, resiliency). Some evidence suggests that local management actions, particularly of fisheries (specifically, no-take marine reserves) and watersheds, can enhance the ability of species, communities, and ecosystems to tolerate climate change-

related stressors, and potentially delay reef loss by at least a decade under “business-as-usual” rises in GHG emissions (Keller *et al.*, 2008; Kennedy *et al.*, 2013). In the Caribbean especially, local regulation of fisheries for herbivorous fish species (specifically parrotfish) is deemed one of the most important local actions to safeguard coral reefs in the face of looming climate change threats (Jackson *et al.*, 2014). It also has been strongly suggested that local management be combined with a low-carbon economy to prevent further degradation of reef structures and associated ecosystems (Birkeland *et al.*, 2013; Kennedy *et al.*, 2013).

After considering this supplemental information in addition to that which was available for the proposed rule, our conclusion regarding the inadequacy of regulatory mechanisms addressing global threats to corals from GHG emissions remains unchanged from the proposed rule. That is, without any substantive changes in emissions reduction pledges from any major economies and without any noteworthy additional efforts to actually reduce GHG emissions, the supplemental information considered in this final rule regarding regulatory mechanisms does not change the previous analysis. We reach the same conclusions regarding local regulatory mechanisms as described in the proposed rule, with the exceptions of *Acropora palmata* and *A. cervicornis*. For these species, we have incorporated into this final rule, the analysis of adequacy of regulatory mechanisms included in the 2005 status review and 2006 listing of these species as threatened. Those documents concluded that existing regulatory mechanisms are inadequate to address local and global threats affecting these species, and as such are contributing to the threatened status of these species.

Because the local threats have impacted and continue to impact corals across their ranges, we still generally conclude that, collectively, the existing regulations are not currently preventing or controlling local threats across the entire range of any of the 65 species. We still do not have sufficient information to determine if an individual species’ extinction risk is exacerbated by inadequacy of individual existing regulations. On the other hand, the best available information suggests that local management may confer resilience benefits for coral reefs on an ecosystem level, which could extend the timeframe at which individual coral species may be at risk of extinction by providing a protective temporal buffer in the face of climate change-related threats. That is, implementing effective local

management actions may allow for coral to persist while awaiting significant global progress to curb GHGs. Overall, we maintain that in the absence of effective global regulatory mechanisms to reduce impacts from climate change to corals, the inadequacy of existing regulatory mechanisms at global and local scales poses an extinction risk threat to all of the corals that are vulnerable to climate-related threats.

#### *Threats Evaluation Conclusion*

The above information on threats to reef-building corals leads to several important overall points that apply both currently and over the foreseeable future. First, the period of time over which individual threats and responses may be projected varies according to the nature of the threat and the type of information available about that threat and the species’ likely response. The threats related to global climate change pose the greatest potential extinction risk to corals and have been evaluated with sufficient certainty out to the year 2100. Second, we expect an overall increase in threats, especially those related to global climate change as projected by RCP8.5 to 2100. Third, RCP8.5’s projections of conditions on coral reefs within the ranges of the species covered by this rule over the foreseeable future are based on spatially-coarse analyses associated with high uncertainty, in particular at local spatial scales. Finally and most importantly, determining the effects of global threats on an individual coral species over the foreseeable future is complicated by the combination of: (1) Uncertainty associated with projected ocean warming and acidification threats; (2) regional and local variability in global threats; (3) large distributions and high habitat heterogeneity of the species in this final rule; and (4) limited species-specific information on responses to global threats.

Thus, in our species determinations, we recognize that the best available information indicates the impacts of climate change will likely increase in the foreseeable future. However, there are limitations to using this global, coarse-scale information for determining vulnerability to extinction for individual coral species. Climate change projections over the foreseeable future are associated with three major sources of uncertainty; (1) The projected rate of increase for GHG concentrations; (2) strength of the climate’s response to GHG concentrations; and (3) large natural variations. The recent warming slow-down is an example of a large natural variation that was not anticipated by previous models. Reports

that discuss the future impacts of climate change on coral reefs indicate variability in both the models underlying these changes and the extent of potential impacts to the coral ecosystem. Recognizing uncertainty and spatial variability in climate change projections, and the spatial variability in environmental conditions on coral habitat, in our species determinations we emphasize the role that heterogeneous habitat and spatial and demographic traits play in evaluating extinction risk. We also consider in our determinations that each species in this final rule experiences a wide variety of conditions throughout its range that helps mitigate the impacts of global and local threats to some degree. Finally, we don’t consider projections of impacts to coral reef ecosystems to definitively represent impacts to individual coral species, because coral reef communities typically consist of dozens to hundreds of reef-building coral species, each of which may respond differently to environmental and ecological changes. In addition, reef-building corals are not limited to occupying only coral reefs.

#### **Risk Analyses**

Many factors can contribute to an individual species’ extinction risk. The process of extinction usually occurs in phases, first affecting individual populations or sub-populations, and then progressing to the species level. Extinction can occur as a result of stochastic processes that affect birth and death and mortality from catastrophic events. A species’ biological traits can influence extinction risk both in terms of vulnerability to environmental perturbations and effects on population dynamics. Extinction risk is also influenced by compensatory effects, which are self-reinforcing processes (*i.e.*, positive feedbacks) that accelerate species loss as its population density declines.

The proposed rule described our framework for evaluating extinction risk and making listing determinations in the Risk Analyses section. There were multiple steps in our process of evaluating the listing status of each species. The initial step in developing the framework consisted of evaluating the ESA definitions of “endangered” and “threatened” and how those definitions apply to corals. The application of those definitions was based on the background of the Context for Extinction Risk and General Threats sections of the proposed rule.

We then considered the elements that contribute to the extinction risk of corals in the Risk Analyses section of the proposed rule. The following is a list

of the specific elements within their respective categories: (1) Vulnerability to threats, including each of the nine most important threats, based on a species' susceptibility and exposure to each of the threats; (2) demography, including abundance, trends in abundance, and relative recruitment rate; and (3) spatial structure, including overall distribution, which is a combination of geographic and depth distributions, and ocean basin. In order to evaluate the best available information for each of the 82 candidate corals and consider all elements in each of these categories, we developed a Determination Tool to organize and consistently interpret the information in the SRR, FMR, and SIR and apply it to the definitions of threatened, endangered, and not warranted species developed for corals, in a decision framework that we developed to specifically apply to corals.

In the proposed rule, we linked the major elements of our Risk Analyses, vulnerability to threats, demography, and spatial structure, to the ESA listing categories. We described endangered species as having a current extinction risk; they are highly vulnerable to one or more of the high importance threats and have either already been seriously adversely affected by one of these threats, as evidenced by a declining trend and high susceptibility to that threat, or they lack a buffer to protect them from serious adverse effects from these threats in the future. We described threatened species as not currently being in danger of extinction, but are likely to become so within the foreseeable future. They are highly or moderately vulnerable to one or more of the high importance threats or highly vulnerable to one or more of the lower importance threats, but have either not yet exhibited effects in their populations or they have the buffering protection of more common abundance or wider overall distribution. We described not warranted species as not being in danger of extinction currently and not likely to become so within the foreseeable future because they have: Low vulnerability to the high importance threats, or low or moderate vulnerability to all the lower importance threats, and common abundance or wide overall distribution.

The proposed rule described the basis for our determination of the foreseeable future for the purposes of projecting climate-related threats in the Threats Evaluation and Risk Analyses sections, and was supported by several other sections (e.g., Global Climate Change—Overview). Consistent with our practice for all species listing determinations, we established that the appropriate period

of time corresponding to the foreseeable future is a function of the particular type of threats, the life-history characteristics, and the specific habitat requirements for the coral species under consideration. The timeframe established for the foreseeable future considered the time necessary to provide for the conservation and recovery of each threatened species and the ecosystems upon which they depend. It was also a function of the reliability of available data regarding the identified threats and extends only as far as the data allow for making reasonable predictions about the species' response to those threats. We agreed with the BRT's assessment that the threats related to climate change had been sufficiently characterized and predicted through the end of this century. Therefore, in the proposed rule, we determined the year 2100 to be the appropriate outer limit of foreseeability as to climate change-related threats.

In the proposed rule, we evaluated each species throughout its entire range, because no SPOIRs were identified, and that assessment has not changed in the final rule as described further below in the Statutory Standards sub-section. While we did receive additional qualitative information on the abundances and distributions of the 65 proposed species, nothing in that data indicated that any portions of the range of any of the species warranted further evaluation under the applicable standards of the final SPOIR Policy, as discussed in the Statutory Standards sub-section below. The last step in developing the proposed listing determinations was to evaluate "Conservation Efforts" to determine if they would change the basis for listing a species by alleviating threats or recovering populations. We concluded that conservation efforts on global and local scales did not change the status determined using our decision framework for any of the 82 candidate species.

Comments 32–34 and 37–42 focused on four aspects of the listing determination process in the proposed rule: (1) The Determination Tool, (2) the foreseeable future, (3) the SPOIR analysis, and (4) conservation efforts. The comments we received identified deficiencies in the proposed rule's Determination Tool, leading to a change in our approach from a formulaic framework to describe extinction risk, to a non-formulaic framework to describe vulnerability to extinction. That is, the final determination framework integrates different types of information in a holistic manner that better represents all the available information,

including complexity and uncertainty, than was possible using the linear Determination Tool in the proposed rule. In this section, we explain the final determination framework process that we used to determine each of the species' statuses, how it is different from the proposed rule, and how new and supplemental information was incorporated.

In the proposed rule we described our determination approach in the Risk Analyses and Detailed Description of Determination Tool Elements sections, in which we discussed the elements that affect a coral's extinction risk. Below we describe how that determination approach has been adapted for this final rule and applied to the Statutory Standards, in light of and in response to public comments.

#### *Final Determination Framework*

*Overview of Key Changes Applied in Final Determinations.* We received many comments questioning the accuracy of the methods used to analyze the available information to assess extinction risk and derive listing statuses for each of the proposed species, including how the Determination Tool was used. After considering these comments, and as discussed above, our findings in the proposed rule were influenced by how we believed coral species would react to environmental changes now and over the foreseeable future. Given the current effects and projections of climate change impacts to the marine environment into the foreseeable future and the information we had at the time of the proposed rule on coral response to existing and predicted environmental stressors, we determined that many of the coral species met the definition of "endangered species" or "threatened species." In explaining how the Determination Tool assessed risk and derived listing statuses we concluded that, as some public comments suggested, the Determination Tool was too linear and deterministic. This led to listing determinations in the proposed rule that were based, in large part, on applying the endangered and threatened standard to relative characteristics instead of applying the endangered and threatened standard to each individual species independently to determine their listing status.

In this rule, we have changed our determinations for many of the species for two general reasons: (1) Informed by public comments, we refined the way we apply the available information to determine vulnerability to extinction; and (2) we received via public comments, or gathered ourselves,

information that expanded our existing knowledge.

We received and gathered specific information about spatial, demographic, and other characteristics of individual coral species, and the public comments provided general scientific criticism about how we weighed these factors. In the proposed rule, we gave greater consideration to susceptibility to threats but did not fully recognize the extent to which spatial, demographic, and other characteristics of corals can moderate vulnerability to extinction. After considering all of the available information and public comments, in this final rule we continue to recognize the threats that the species face, but we also place more emphasis on buffers against those threats and revisit the predicted population responses of individual species to the threats, giving full consideration to their current spatial, demographic, and other characteristics. For example, we took into account that many of the species, when viewed on their own rather than in relation to other coral species or vertebrate species, have more substantial absolute abundances than the prior methodology accounted for.

We also took into account that in many instances coral species occupy a wide range of habitats, including areas that can act as refugia from warming, which moderate the predicted impacts across coarse-scale areas. As explained generally above, and in regard to individual species below, the species in this final rule will be negatively impacted by future conditions, but in light of our consideration of factors and characteristics discussed above, we find they are not currently in danger of extinction and do not meet the definition of endangered. We do, however, conclude that some species are likely to become in danger of extinction within the foreseeable future and thus meet the definition of threatened. We also find that listing is not warranted for some species that were previously proposed for listing.

In this final rule, we acknowledge that there are no recipes or formulas for endangered, threatened, or not warranted coral species, especially given the variability in coral species' biology and ecology, and the variability in available information from species to species. Accordingly, the final framework allows for consideration of each coral's circumstances as a whole (simultaneously evaluating each species' demography, spatial characteristics, threat susceptibilities, and current and future environmental conditions independently of the other species), leading us to species-specific

conclusions about vulnerability to extinction.

The final determination framework used in this final rule is composed of seven elements. The first element is describing the statutory standards. The second, third, fourth, and fifth elements are identifying and analyzing all the appropriate species-specific and general characteristics that influence extinction risk for a coral species. The sixth element is relating a species' characteristics to a particular extinction risk at appropriate spatial and temporal scales. The seventh element is explicitly stating how each species' extinction risk meets the statutory listing definitions as applied to corals, resulting in an ultimate listing status. A final consideration in evaluating listing status is whether current or planned conservation efforts improve the overall status of any of the 65 species such that the additional protections of the ESA are not warranted.

In moving to an integrated, non-formulaic framework, some of our key assumptions about vulnerability to extinction changed due to analyzing the different aspects of each species' characteristics independently (on an absolute scale), instead of being rated with the other proposed corals species (on a relative scale). We rely on the following guiding principles extracted from each of the sections in the first part of this rule, providing the context and background information for the species determinations, in order to determine each species' listing status:

- Clonal, colonial organisms, such as corals, are vastly different in their biology and ecology than many other species listed by NMFS under the Endangered Species Act.

- In our species determinations, we give appropriate consideration to the complex nature of coral biology and variability in responses to threats between individual coral colonies and even between different portions of the same colony.

- In our species determinations, absolute abundance and absolute distribution inform our evaluation of a species' current status and its capacity to respond to changing conditions over the foreseeable future.

- The concept of heterogeneous habitat influences extinction risk for all species in this final rule because each species experiences a wide variety of conditions throughout its range, which allows for variable responses to global and local threats.

- We recognize that the best available information indicates the impacts of climate change will likely increase in the foreseeable future. However, there

are limitations to using this global, coarse-scale information for determining vulnerability to extinction for individual coral species.

- In our species determinations, we don't consider projections of impacts to coral reef ecosystems to definitively represent impacts to individual coral species, because coral communities typically consist of dozens to hundreds of coral species, each of which may respond differently to environmental and ecological changes.

- Recognizing the uncertainty and spatial variability in climate change projections, and the spatial variability in environmental conditions on coral habitat, in our species determinations we emphasize the role that heterogeneous habitat and absolute demographic and spatial characteristics play in evaluating extinction risk.

We have ordered the informational categories in the Species-specific Information and Determinations sections below for clarity in describing the species-specific elements and their interaction in contributing to each species' vulnerability to extinction as follows: (1) Spatial Information—overall distribution and ocean basin, habitat; (2) Demographic Information—abundance, trends in abundance, relative recruitment rate; and (3) Susceptibility to threats based on a species' susceptibility to each of the nine threats. Further, when information is available that does not fall into one of the categories or elements identified above, but is relevant to extinction risk, we provide it under the Other Biological Information category. In each species determination, we refer back to the specific guiding principles that played a role in how we consider the species-specific information and the sections in which they are described in more detail.

#### *Statutory Standards*

The definitions of endangered and threatened species under section 3 of the ESA, wherein (1) an "endangered species" is defined as "any species which is in danger of extinction throughout all or a significant portion of its range", and (2) a "threatened species" is defined as "any species which is likely to become an endangered species in the foreseeable future throughout all or a significant portion of its range," formed the basis of our determination framework. Considered at both the spatial and temporal scales applicable to each of those listing statuses, an endangered species *currently* faces an extinction risk throughout *all or a significant portion of its range* and a threatened species is likely to become endangered throughout

all or a significant portion of its range within the foreseeable future. In other words, the primary statutory difference between a threatened and endangered species is the timing of when a species may be in danger of extinction, either presently (endangered) or in the foreseeable future (threatened). Further, as discussed below, no significant portions of their ranges could be determined for any of our proposed species; thus, the only spatial scale we consider is each species' entire range.

Court opinions produced in litigation challenging the listing of the polar bear as threatened provides a thorough discussion of the ESA's definitions and the Services' broad discretion to determine on a case-by-case basis whether a species is in danger of extinction (see, *In Re Polar Bear Endangered Species Act Listing and § 4(d) Rule Litigation*, 794 F. Supp.2d 65 (D.D.C. 2011); *aff'd*, 709 F.3d 1 (D.C. Cir. 2013); 748 F. Supp.2d 19 (D.D.C. 2010)). The Court determined that the phrase "in danger of extinction" is ambiguous. The Court held that there is a temporal distinction between endangered and threatened species in terms of the proximity of the "danger" of extinction, noting that the definition of "endangered species" is phrased in the present tense, whereas a threatened species is "likely to become" so in the future. However, the Court also ruled that neither the ESA nor its legislative history compels the interpretation of "endangered" as a species being in "imminent" risk of extinction. Thus, in the context of the ESA, a key statutory difference between a threatened and endangered species is the timing of when a species may be in danger of extinction, either now (endangered) or in the foreseeable future (threatened). The Court ruled that although imminence of harm is clearly one factor that the Services weigh in their decision-making process, it is not necessarily a limiting factor, and that Congress did not intend to make any single factor controlling when drawing the distinction between endangered and threatened species. In many cases, the Services might appropriately find that the imminence of a particular threat is the dispositive factor that warrants listing a species as 'threatened' rather than 'endangered,' or vice versa. To be listed as endangered does not require that extinction be certain or probable, and that it is possible for a species validly listed as "endangered" to actually persist indefinitely. Due to the ambiguous nature of the statutory terms, we have defined "endangered" and "threatened" at the end of the

Foreseeable Future sub-section below in the context of the particular species (corals) being considered for listing.

*Significant Portion of its Range (SPOIR)*. The ESA's definitions of "endangered species" and "threatened species" refer to two spatial scales, providing that a species may be imperiled "throughout all" of or "in a significant portion of" its range. 16 U.S.C. 1532(6); (20). NMFS has interpreted the "significant portion of its range" language in a policy that has recently been finalized. See "Final Policy on Interpretation of the Phrase 'Significant Portion of its Range' in the Endangered Species Act's Definitions of 'Endangered Species' and 'Threatened Species'" (79 FR 37578; July 1, 2014) ("Final Policy"). In developing our proposed rule, our analysis was informed by the Draft Policy that was published in December 2011 (76 FR 76987; December 9, 2011). As we explained in the proposed rule, we were unable to identify any portions of the species' ranges that might require closer analysis as potential SPOIRs, due in large part to a lack of species-specific information regarding abundance, geographic distribution, diversity, and productivity (77 FR 73247).

The Final Policy, which we must now apply, differs in two key respects from the Draft Policy. Neither changes the ultimate result in this case, which is that no SPOIRs can be identified. First, the Final Policy specifies that no portions of a species' range can be "significant," and thus no SPOIR analysis need be done, where the range-wide status analysis leads to a conclusion that listing the entire species as threatened or endangered is warranted. (Under the Draft Policy, even if a species were found to warrant listing as "threatened," the agency still needed to consider whether any portions of the range may be significant). Second, the final policy defines "significant" to include not only those portions where the individuals are so biologically significant that without them the entire species would meet the definition of "endangered" (the standard in the Draft Policy), but also those portions whose loss would render the species "threatened."

In this case, our framework evaluates each species throughout its range to determine extinction risk. If a species is determined to be threatened or endangered based on the rangewide analysis, no further evaluation is warranted. However, if a species is found to be not warranted at the spatial scale of its entire range, we must consider if a SPOIR exists that may be both highly biologically important and

at higher extinction risk, such that its loss would render the entire species endangered or threatened. An evaluation is required only where there is information to suggest that a particular portion of the range is likely to be both "significant" as defined in the policy and to qualify as endangered or threatened (79 FR 37586).

As described in the proposed rule, the BRT did not identify any portions of the range for any of the 82 coral species as being potentially "significant" or at a higher extinction risk. Because there was a general lack of species-specific data regarding quantitative abundance, distribution, diversity, and productivity of coral species, we were not able to identify any portions of any of the species' ranges that could be considered unusually biologically significant. Further, we had no information to indicate that particular local threats were more severe in a particular portion of an individual species' range.

No supplemental information was received in response to the proposed rule that provides support for identification of a SPOIR for any of the proposed species. While we did receive supplemental information on the qualitative abundances and distributions for some species, nothing in that data suggests that any particular portion of any proposed species range is unusually biologically significant. We do not have any information that would help elucidate whether any species is at higher exposure to threats in a particular area of its range (*i.e.*, where threats may be so acute or concentrated that current conditions are likely to render the species there at significantly higher risk of extinction than the overall species). Thus, we did not identify any SPOIR for any species, and so our determination as to each species is based on the best available information about the species' status throughout its range.

*Foreseeable Future*. The "foreseeable future" is integral to the definition of a threatened species. It is the timeframe over which we evaluate a species' extinction risk if it is not currently in danger of extinction. As described in the proposed rule, the identification of the foreseeable future is unique to every listing decision. It is based on the particular type of threats, the life-history characteristics, and the specific habitat requirements for the species under consideration.

For this Final Rule, we clarify that the "foreseeable future" is that period of time over which we are able to make reliable projections about all of the significant threats affecting the species and the species' likely response to those

threats. Projections need not be “certain” to be reliable, so long as we are able to make predictions with a reasonable degree of confidence based on available information. In the proposed rule, we identified the year 2100 as marking the outer limit of the foreseeable future based upon the ability to make projections about the primary threats to corals—those stemming from global climate change—over that period (77 FR 73226). However, in identifying 2100 as the limit of the foreseeable future for purpose of analyzing those threats, we did not intend to establish that year as the only relevant benchmark for analyzing all threats to the species or the species’ response thereto.

Because neither the ESA nor implementing regulations define “foreseeable future,” the term is ambiguous, and Congress has left broad discretion to the Secretary to determine what period of time is reasonable for each species. This does not require identifying a specific year or period of time to frame our analysis, particularly where there is inadequate specific data to do so. See “Memorandum Opinion: The Meaning of ‘Foreseeable Future’ in Section 3(20) of the Endangered Species Act” (M–37021, Department of the Interior Office of the Solicitor, January 16, 2009). The appropriate timescales for analyzing various threats will vary with the data available about each threat. In making our final listing determinations we must synthesize all available information and forecast the species’ status into the future only as far as we reliably are able based on the best available scientific and commercial information and best professional judgment.

In the case of corals, we can make reasonable assessments as to the most significant environmental factors facing the coral species between now and 2100. We have explained that this time period, which is consistently used by most current global models and the IPCC reports, allows for reliable and reasonable projections about climate change-related threats. As described in the Threats Evaluation—Foreseeable Future and Global Climate Change Overview sections above, 2100 was selected as the limit of foreseeability for climate change-related threats based on AR4’s and AR5 WGI’s use of 2100 as the end-point for most of its global climate change models (IPCC, 2013). Public comments asserted that the models used in climate predictions are too uncertain to reliably predict climate conditions out to 2100. However, as we have explained in our response to Comment 38 and elsewhere in this final rule, supplemental information supports, and

we reaffirm our choice of, identifying 2100 as the timeframe over which we can make reliable predictions about climate change-related threats.

However, global climate change is not the only relevant threat to the species, and the range of available data differs as to these other threats (such as predation, sedimentation, *etc.*). Further, in reaching our conclusions and ultimate listing determinations, we need to assess how the species will react to the various stressors identified in this rule. For example, to the extent it was available, we considered a significant amount of information on the current spatial and demographic features of the species, based on various types of information which support varying degrees of projection into the future. Thus, while the year 2100 is a reliable end-point for projecting climate change-related threats, it is not valid across the range of threats for the species and should not be misunderstood as driving our forecasts of the species’ statuses.

For all of these species, we concluded based on the best available scientific and commercial information that their spatial, demographic, or other characteristics buffer them against current endangerment of extinction. However, over the foreseeable future, the ability of spatial and demographic traits to provide a buffer against the danger of extinction is expected to diminish as colonies within particular areas are impacted due to climate change and other negative stressors. We considered, at a species level, whether these predicted conditions may cause the species to become in danger of extinction within the foreseeable future. However, there are varying degrees of certainty about the responses of corals to stressors. We can be confident that certain mitigating elements of the life history for some of these species will not change, such as their ability to reproduce asexually or the ability to persist in a range of depths. But we are less confident in other aspects, such as precisely where and when local extirpations may occur.

For this final rule, then, we make clear that our listing determinations are reached on the totality of the best available information about the threats to the species and the species’ likely response to them over time. Our determinations reflect our consideration of that information, as well as application of our professional judgment regarding how far into the future we can reliably project either the underlying threats or the species’ response. However, in light of the number of variables pertaining to the stressors and buffering traits among the

corals species evaluated, and the limited availability and incomplete nature of quantitative data on these species, a quantitative assessment of these projections is not possible. Therefore our assessment of the foreseeable future is necessarily qualitative. Given the biological traits and life history strategies of the corals evaluated in this rule, including their relatively long life-spans, the period of time over which we are able to make reliable projections is the next several decades. This general timeframe thus frames our listing determinations. Although we recognize that climate related threats will persist beyond this horizon, we find it both infeasible on the information available and unnecessary to attempt to identify the foreseeable future across the full range of threats to the species and the species’ response with more precision.

In the proposed rule, we considered how the temporal scales were appropriately factored into our evaluations of whether a species was in danger of extinction now, likely to become in danger of extinction in the foreseeable future, or not warranted for listing. For example, two major factors determining the immediacy of the danger of extinction for corals are the relatively high degree of certainty of impacts from high importance threats and a species’ current or future capacity to resist adverse effects. Under the proposed rule’s Determination Tool approach, endangered species were species with a current high extinction risk; they were highly vulnerable to one or more of the high importance threats and had either already been seriously adversely affected by one of these threats, as evidenced by a declining trend, and high susceptibility to that threat, or they lacked a buffer to protect them from serious adverse effects from these threats in the future. While a threatened species under the proposed rule might be impacted by the same threats as an endangered species, it was less exposed or less susceptible, providing greater buffering capacity to those same threats when compared to an endangered species.

In response to public comments critical of our equating species’ listing statuses with outcomes of the determination tool, here we more fully explain the biological characteristics and distinctions between endangered and threatened corals, and corals not warranting listing under the ESA. Under the final rule’s determination framework, an endangered species is at such risk of extinction, that it is currently “in danger” of extinction throughout its range. As such, an endangered coral species is of such low

abundance or is so spatially fragmented that the species is currently in danger of extinction. Several processes may contribute to the danger of extinction (*e.g.*, depensatory process, catastrophic events). Depensatory processes include reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding. A coral species with these characteristics would be vulnerable to background environmental variation if a large proportion of the existing population were concentrated in an area that experienced an environmental anomaly leading to high mortality. Similarly, an endangered coral species could be of such low abundance that one catastrophic event or a series of severe, sudden, and deleterious environmental events could cause mortality of a large enough proportion of the existing population that the remaining population would be unable to reproduce and/or recover. A coral species that meets the endangered standard is not necessarily characterized by a single factor (*e.g.*, abundance number, density, spatial distribution, or trend value) but could also be characterized by combinations of factors encompassing multiple life history characteristics and other important ecological features, as described above. Different combinations of such factors may result in endangered status from species to species.

Under the final rule's determination framework, a threatened coral species also is at a risk of extinction due to its spatial and demographic characteristics and threat susceptibilities; however those traits still provide sufficient buffering capacity against being in danger of extinction currently. In other words, the species has an abundance and distribution sufficient for it to be not currently of such low abundance or so spatially fragmented to be in danger of extinction, but is likely to become so within the foreseeable future throughout its range. Similar to an endangered species, a coral species that meets the threatened standard is not necessarily characterized by a single factor (*e.g.*, abundance number, density, spatial distribution, or trend value) but could also be characterized by combinations of factors encompassing multiple life history characteristics and other important ecological features, as described above. Different combinations of such factors may result in threatened status from species to species.

Thus, there is a temporal distinction between endangered and threatened species in terms of the proximity of the danger of extinction based on the sufficiency of characteristics to provide

buffering capacity against threats that cause elevated extinction risk. It is worth noting that this temporal distinction is broad, and a threatened species could likely become an endangered species anytime within the foreseeable future.

Under the final rule's determination framework, a coral species that is not warranted for listing has spatial and demographic traits and threat susceptibilities that, when considered in combination, provide sufficient buffering capacity against being in danger of extinction within the foreseeable future throughout its range. In other words, it has sufficient abundance and distribution, when considering the species' threat susceptibilities and future projections of threats, it is not likely to become of such low abundance or so spatially fragmented to be in danger of extinction within the foreseeable future throughout its range. A not warranted species also may not be susceptible to the threats at a sufficient level to cause any major change in the species abundance.

In summary, the basic structure of our final determination framework is formed by the relevant spatial and temporal scales over which each coral species' extinction risk is evaluated. An endangered coral species is *currently* in danger of extinction throughout its entire range. A threatened species is *likely to become* endangered throughout its entire range within the foreseeable future.

#### *Spatial Structure*

We consider spatial elements that increase a species' risk of extinction, alone or in combination with other threats, under ESA Factor E—other natural or manmade factors affecting the continued existence of the species. Spatial structure is important at a variety of scales. At small spatial scales within a single population, issues of gamete density and other Allee effects can have significant impacts on population persistence. At large spatial scales, geographic distribution can buffer a population or a species from environmental fluctuations or catastrophic events by "spreading the risk" among multiple populations. We explicitly described how exposure to individual threats varies at different spatial scales in the Threats Evaluation section above. Generally, having a larger geographic or depth distribution provides more potential area to occupy. However, if populations become too isolated gene flow and larval connectivity may be reduced, making the species less likely to recover from mortality events. Thus, a robust spatial

structure includes larger geographic distributions with adequate connectivity to maintain proximity of populations and individuals within the range. We consider geographic distribution and depth distribution (and connectivity, when we have that information) in describing the overall distribution for each species.

We also consider the ocean basin in which a species exists. As described in the Corals and Coral Reefs—Inter-basin Comparisons, the Indo-Pacific occupies at least 60 million square km of water (more than ten times larger than the Caribbean), and includes 50,000 islands and over 40,000 km of continental coastline, spanning approximately 180 degrees of longitude and 60 degrees of latitude. Thus, occupying only a small portion of the Indo-Pacific basin can still be a geographically large distribution for an individual coral species. In contrast, the Caribbean basin is relatively geographically small and partially enclosed, but biologically well-connected. The Caribbean also has relatively high human population densities with a long history of adversely affecting coral reef systems across the basin. In the proposed rule we determined that if a species is restricted to the Caribbean, its overall range was considered narrow and its extinction risk was significantly increased, which greatly contributed to an endangered or threatened determination. Comment 40 criticizes our characterization of the Caribbean in this manner, stating that the BRT's determination that the entire Caribbean is sufficiently limited in geographic scale to be a factor that increases the extinction risk of all corals in the Caribbean is at odds with genetic data. The commenter provided references to support the conclusion that, while it is clear that regional-scale processes such as bleaching and disease are acting on all these reefs in the Caribbean basin simultaneously, all reefs should not be presumed to respond the same to these disturbances. Upon consideration of the comment and the fact that the Determination Tool ratings regarding basin occupancy were an inadvertent function of comparing the Caribbean basin to Indo-Pacific basin (*i.e.*, the automatic increase in extinction risk for species occurring in the smaller, more disturbed Caribbean was only relative in comparison to species occurring in the larger, less disturbed Indo-Pacific) we re-evaluated our characterization of the Caribbean. We now consider the absolute (non-relative) size of the basin and the amount of heterogeneity in the system; therefore, we no longer

conclude that presence within the Caribbean basin automatically increases extinction risk (because many of the Caribbean coral species occupy a large portion of habitat compared to the total habitat available to them and the heterogeneous nature of that habitat). In general, we still consider distribution in the Caribbean to be problematic, but will now consider the influence of a Caribbean distribution on extinction risk on a species-by-species basis. For example, if a species has a Caribbean-wide geographic distribution and large depth distribution, and isn't susceptible to or exposed to threats now or through the foreseeable future, then a Caribbean basin distribution alone doesn't automatically increase the species' extinction risk. In the Species-specific Information and Determinations section of this final rule, we describe the extent to which an individual species' extinction risk is influenced by its specific geographic, depth, and habitat distributions within each basin.

#### *Demography*

Demographic elements that cause a species to be at heightened risk of extinction, alone or in combination with threats under other listing factors, are considered under ESA Factor E—other natural or manmade factors affecting the continued existence of the species. In the proposed rule, we used species-specific qualitative abundance estimates, coded as “common,” “uncommon,” or “rare” for the candidate species because it was the only abundance metric that was available for all of the 82 candidate species. As mentioned above in the Distribution and Abundance of Reef-building Corals sub-section, these qualitative estimates are the subjective opinion of particular authors on their particular survey data and are meant to indicate relative abundance between the categories. That is, a rare species has fewer individuals as compared to an uncommon one, and an uncommon species has fewer individuals than a common one. These estimates are also meant to describe an author's opinion of the qualitative abundance of the species throughout its range, but not an estimate of the abundance at an individual location. In general, “rare” or “uncommon” species are more vulnerable than “common” ones, although some species are naturally rare and have likely persisted in that rare state for tens of thousands of years or longer. However, naturally rare species can be at greater risk of extinction than naturally more common species when confronted with global threats to which they are vulnerable. In our final

determination framework, rarity or uncommonness may increase extinction risk, but alone it does not automatically contribute to a finding of an endangered or threatened status.

Trends in abundance directly demonstrate how a particular species responds under current or recent-past conditions. Generally, a continuing downward trend likely increases extinction risk, while stabilization or a continuing upward trend likely decreases extinction risk. Trend data for the 65 species are scarce, but we describe the extent to which an individual species' extinction risk is influenced by its trend data when the information is available.

Productivity is another important indicator of extinction risk. Productivity is defined here as the tendency of the population to increase in abundance and is often expressed as “recruits per spawner,” although the term “recruit” can be difficult to apply in the case of corals, which reproduce both sexually and asexually (see Individual Delineation sub-section). Some of the proposed coral species are long-lived, with low or episodic productivity, making them vulnerable to trends of increased mortality or catastrophic mortality events. Overall, recruitment rate estimates for the proposed species are scarce, but in cases where estimates were available analysis of how that species' extinction risk is influenced by its relative recruitment rate is considered in the Species-specific Information and Determinations section below.

#### *Susceptibility to Threats*

Susceptibility of a coral species to a threat is primarily a function of biological processes and characteristics, and can vary greatly between and within taxa. Susceptibility of a species to a threat depends on the combination of: (1) Direct effects of the threat on the species; and (2) the cumulative and interactive (synergistic or antagonistic) effects of the threat with the effects of other threats on the species. In the proposed rule, we considered how the cumulative or interactive effects altered the rating assigned to a threat susceptibility in isolation. However, upon further consideration, we need to evaluate the extent to which one threat influences the susceptibility of an individual species to another threat with more species-specific information, in connection with all the other elements that influence a species' extinction risk. Generally, cumulative and interactive processes are complex and uncertain and existing information about threats interactions is only based

on a few studies on a few species. Where possible, when we have species-specific cumulative or interactive effects information, we have applied this information to that particular species' susceptibilities in a more integrated manner. Species-specific threat susceptibilities are described in the Species-specific Information and Determinations section.

The three most important threats that contribute to the proposed coral species' extinction risk are ocean warming, disease, and ocean acidification. We considered these threats to be the most significant threats posing extinction risk to the proposed coral species currently and out to the year 2100. Threats of lower importance (trophic effects of reef fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade) also contributed to our findings on extinction risk, but to a lesser extent.

#### *Current and Future Environmental Conditions*

The general information described in the preceding sections of this final rule illustrates that the most important threats are currently increasing and likely to increase further in the foreseeable future (Threats Evaluation), but that the impacts from these threats currently and in the foreseeable future are difficult to interpret and do not necessarily correlate to an increased vulnerability to extinction due to the biological and physical complexity of corals and their habitat (Corals and Corals Reefs, Threats Evaluation).

The information on corals, coral reefs, coral habitat, and threats to reef-building corals in a changing climate leads to several important points that apply both currently and over the foreseeable future. First, the foreseeable future for purposes of our ultimate listing determinations is described qualitatively and encompasses the next several decades. For purposes of analyzing the specific threats related to climate change, we have identified the foreseeable time period over which we can make reliable projections to extend over the period from now to the year 2100. There is increased uncertainty over that time period as conditions that are analyzed closer to the year 2100 become less foreseeable. That is, the general trend in conditions during the period of time from now to 2100 is reasonably foreseeable as a whole, but conditions become more difficult to accurately predict through time. Second, there is an overall increasing trend of threat severity, especially for threats related to global climate change as projected by RCP8.5 to 2100. Third, while some models suggest disastrous

effects of RCP8.5 on coral reefs by 2100, such projections are based on spatially coarse analyses associated with high uncertainty, especially at local spatial scales. In sum, determining the effects of global threats on an individual coral species over the foreseeable future is complicated by the combination of: (1) Uncertainty associated with projected ocean warming and acidification threats; (2) regional and local variability in global threats; (3) large distributions and high habitat heterogeneity of the species in this final rule; and (4) limited species-specific information on responses to global threats.

#### *Vulnerability to Extinction*

The vulnerability of a species to extinction is a complex function of physiology, life history, morphology, spatial distribution, and interaction with threats (the biological context). The biological context for a species' vulnerability to threats dictates the ecological interactions that ultimately determine how a species responds to threats, such as competition and predation (the ecological context). For example, a species that suffers high mortality from a bleaching event also may be able to recover quickly because its high dispersal and skeletal growth enable efficient recolonization and strong competition. Thus, the initial response to threats does not necessarily mean the species is vulnerable.

Vulnerability of a coral species to extinction also depends on the proportion of colonies that are exposed to threats and their different responses to those threats. In the proposed rule there was little variation between species for exposure to a given threat in the assigned ratings (*e.g.*, exposure to ocean warming was rated the same for all 82 species, which should not automatically be the case because for species that have drastically different distributions and abundances). For this final rule, a coral species' vulnerability to extinction is now evaluated to be holistically influenced by its demographic and spatial characteristics, threat susceptibilities, and current and future environmental conditions. We believe this more complete and integrated treatment of the factors that influence a coral's vulnerability to extinction will lead to a more accurate characterization of whether or not a species currently faces an extinction risk throughout its entire range.

#### *Species Status*

After analyzing all of the relevant species-specific demographic and spatial characteristics, threat susceptibilities, and general information

on current and future environmental conditions, we relate those characteristics to the particular species' status. This is the key component of the determination that explains how certain species characteristics translate to a particular extinction risk at appropriate spatial and temporal scales. These determinations are heavily influenced by the quantity and quality of species-specific information, especially the species' demographic and distribution characteristics. We received many public comments regarding the lack of quantity and quality of information available for each of the species; those commenters asserted that our species determinations were therefore unfounded. By specifically considering all the currently available species-specific information (both information that we used in the proposed rule and the considerable amount of information that has become available since the proposed rule), we are able to produce more robust evaluations of the information and species determinations. Recognizing the uncertainty and spatial variability of climate change projections and the limited species-specific information on how species in this final rule respond to climate change, we emphasize a species' demographic and spatial characteristics in how its vulnerability to extinction is affected now and through the foreseeable future.

In finalizing a species determination we translate the species' status directly into a listing category using the statutory standards. In the proposed rule, we satisfied this step by using an organizational process called the outcome key, based on ratings in the Determination Tool. The key was intended to identify the general species characteristics and combinations that equate to a particular listing status. However, the outcome key in the proposed rule was too formulaic, and did not explain our comprehensive consideration of the species characteristics that influenced their listing status, and was also based on relative ratings from the Determination Tool. Therefore, the presentation of our final determination framework is more clearly articulated in this final rule by explicitly describing the considerations for each the 65 species in narrative format and how they relate to the statutory standards.

In summary, the determination framework used in this final rule is composed of seven elements. The first element is describing the statutory standards. The second, third, fourth, and fifth elements are identifying and analyzing all the appropriate species-specific and general characteristics that

influence extinction risk for a coral species. The sixth element is relating a species' characteristics to a particular extinction risk at appropriate spatial and temporal scales. The seventh element is explicitly stating how each species' extinction risk meets the statutory listing definitions as applied to corals, resulting in an ultimate listing status. A final consideration in evaluating listing status is whether current or planned conservation efforts improve the overall status of any of the 65 species such that the additional protections of the ESA are not warranted. We explicitly apply the determination framework to each species in our narrative evaluations. This approach provides consistency across all of the 65 final listing determinations, but also produces individual determinations that are independent of the other 65 coral species.

#### *Conservation Efforts*

The effect conservation efforts have on an individual species' listing status is the last consideration in making a final determination. Because many conservation efforts are not species-specific, we provide our analysis of the effectiveness of conservation efforts for corals generally prior to making individual species determinations. Our conclusions regarding conservation efforts in this section apply to all of the proposed species. However, in some cases, we are able to identify species-specific conservation efforts and therefore evaluate them separately in the Species-specific Information and Determinations section.

Section 4(b)(1)(A) of the ESA requires the Secretary, when making a listing determination for a species, to take into account those efforts, if any, being made by any State or foreign nation to protect the species. In evaluating the efficacy of protective efforts, we rely on the Services' joint "Policy for Evaluation of Conservation Efforts When Making Listing Decisions" ("PECE;" 68 FR 15100; March 28, 2003). The PECE requires us to consider whether any conservation efforts recently adopted or implemented, but not yet proven to be successful, will result in improving the species' status to the point at which listing is not warranted, or contribute to a threatened rather than endangered status.

For the proposed rule, we developed a Management Report that identified existing conservation efforts relevant to both global and local threats to corals. A draft of this report was peer reviewed and made available to the public with the SRR in April 2012. At that time, we

requested any new or inadvertently overlooked existing information. The information that we received was incorporated into the Final Management Report (NMFS, 2012b), which formed the basis of our initial PECE evaluation. The information, analysis, and conclusions regarding conservation efforts in the proposed rule and supporting documents apply to this final rule, unless otherwise noted below.

Comments 30–32 focus on our consideration of conservation efforts in the proposed rule. In response to public comments on the proposed rule, we incorporated into our analyses in the final rule relevant information on conservation efforts that are new or that may have been inadvertently omitted or mischaracterized. Thus, this final rule incorporates information we received as a result of the public comment period, identifies existing conservation efforts that are relevant to the threats to the 65 coral species in this final rule, both for global-scale threats to corals linked to GHG emissions and other threats to corals. In particular, we received supplemental information regarding coral reef restoration efforts in Florida and the wider-Caribbean. We also received supplemental information regarding efforts to utilize captive-culture techniques to supplement the coral reef wildlife trade industry and reduce collection pressure on wild coral species. Specifically, we received information regarding Indonesia's mariculture operations as well as efforts in the United States to commercially and recreationally farm corals. This information on coral reef restoration, captive culture efforts for trade purposes, and local conservation efforts as it applies to reef resilience is described further below.

We received some supplemental information regarding the ongoing coral reef restoration efforts being made in South Florida as well as the wider-Caribbean, predominantly for staghorn and elkhorn corals (*Acropora cervicornis* and *A. palmata*, respectively). We briefly mentioned active coral restoration in the proposed rule as an important conservation action for corals, but did not describe these efforts in great detail. Coral reef restoration efforts encompass a variety of activities, and they are increasingly utilized to enhance, restore, and recover coral reef ecosystems and species (Bowden-Kerby *et al.*, 2005; Bruckner and Bruckner, 2001; Lirman *et al.*, 2010b). These activities may include post-ship grounding "triage" (e.g., stabilizing substrate and salvaging corals and sponges), active predator and

algae removal, larval seeding, and active restoration via coral propagation and outplanting activities. As a result of the 2009 American Recovery and Reinvestment Act, Federal funding through NOAA enabled a network of coral nurseries to expand throughout south Florida and the U.S. Virgin Islands to help recover threatened staghorn and elkhorn corals. These types of in-water coral nurseries have proven successful for propagating corals and serving as genetic repositories to help replenish and restore denuded reefs (Schopmeyer *et al.*, 2012; Young *et al.*, 2012). In 2012 alone, it was estimated these nurseries housed 30,000 corals, with more than 6,000 corals outplanted to surrounding reefs (The Nature Conservancy, 2012). Further, successful spawning of these outplanted corals has been reported on several occasions since the first event occurred in 2009 (Coral Restoration Foundation, 2013). Still, it should be emphasized that coral reef restoration should not be expected to recover entire reef tracts or species; rather, coral reef restoration can serve as a complementary tool to other management strategies such as fisheries management, coastal zone and watershed management, marine protected areas, and others. In a comprehensive review of restoration activities conducted in Florida and the wider-Caribbean, Young *et al.* (2012) found that most practitioners recommended that active restoration activities always be conducted in conjunction with robust local and regional management strategies to minimize the impacts of global and local threats. This is because coral reef restoration efforts can prove futile if the initial elements of degradation have not been mitigated (Jaap, 2000; Precht and Aronson, 2006; Young *et al.*, 2012).

As described above in the Threats Evaluation—Collection and Trade section of this rule, we received a significant amount of information regarding the potential conservation benefits of increasing international and domestic commercial and recreational production of corals via significant advances in captive-culture techniques (i.e., mariculture and aquaculture). Specifically, we received supplemental information regarding the mariculture efforts conducted in Indonesia to reduce the amount of corals collected in the wild, thereby potentially reducing the threat of the marine ornamental trade industry on corals and coral reefs. As the largest exporter of corals in the world, shifting from wild-collected corals to captive cultured corals is an important conservation effort for

preserving the integrity of wild reefs and coral species in Indonesia. However, there are still many challenges and obstacles related to captive culture of corals that are detailed in the Threats Evaluation, Trade and Collection section above. Any relevant information regarding this topic has also been incorporated into the analysis of conservation efforts in this final rule.

We received information regarding the role of local management actions and conservation efforts with regard to reef resilience. Conservation projects and programs such as international agreements and memoranda of understanding, coral reef monitoring, voluntary protected areas, restoration activities, and outreach and education initiatives, among others, play an integral role in building and maintaining resilience within coral reef ecosystems as well as raising public awareness. More detailed information regarding local actions as they relate to reef resilience are described above in the Threats Evaluation, Inadequacy of Existing Regulatory Mechanisms section of this final rule.

As described above, we received supplemental information about local conservation efforts since the publication of the proposed rule. However, we did not receive any supplemental information that changes our previous conclusions regarding global conservation efforts to slow climate change-related impacts. After considering this supplemental information in addition to that which was available for the proposed rule, our conclusions regarding conservation efforts remain unchanged. Overall, the numerous coral reef conservation projects are increasing and strengthening resiliency within coral reef ecosystems on a local level, and can provide a protective temporal buffer for corals in the face of climate change related threats. Coral reef restoration activities, particularly of the Caribbean acroporid species, are expected to assist in recovery efforts, but they cannot be considered a panacea. In the absence of effective global efforts to reduce impacts from climate change, there are no conservation efforts currently or planned in the future that are expected to improve the overall status of any of the listed species in this final rule, such that the additional protections provided by the ESA are not warranted.

## Species-Specific Information and Determinations

### Introduction

This section summarizes the best available information for each of the 65

species of coral considered in this final rule. The best available information is comprised of the proposed rule and its supporting documents, and information that we either gathered ourselves or received as a result of public comments. To distinguish between the information on which the proposed rule was based from new or supplemental information, we will only cite the primary literature for new or supplemental information. For clarity, we will distinguish whether the information was identified via public comment or if we gathered it ourselves.

Spatial, demographic, and other relevant biological information, threat susceptibilities, and information on regulatory mechanisms are all presented for each species. Because species-specific information is limited for many of the proposed species, genus-level information is highly relevant to our determinations. Therefore, we provide relevant information for each genus prior to providing the specific information for species within that genus. Specifically, genus-level information on threat susceptibilities is relevant to species when the available genus-level information can be appropriately applied to the species. Therefore, in each genus description, we provide a section that summarizes genus-level threat susceptibility information that was provided in the SRR and SIR, as well as in the public comments and supplemental information. Threat susceptibility conclusions are then provided considering the applicability of the genus-level information to an unstudied species within that genus. These conclusions will be applied, as appropriate, in the appropriate species descriptions.

### Caribbean Species Determinations

#### Genus *Agaricia*

##### Introduction

There are seven species in the genus *Agaricia*, all of which occur in the Caribbean (Veron, 2000). Colonies are composed of plates, which are flat, horizontal, or upright. The latter are usually contorted and fused. Some species such as *A. humilis* and *Agaricia fragilis* tend to be small and somewhat circular in shape while others like *Agaricia lamarcki* and *Agaricia grahamae* can form large, plating colonies.

##### Spatial Information

The SRR and SIR provided the following genus-level information on *Agaricia*'s distribution, habitat, and depth range: *Agaricia* can be found at

depths of 50 to 100 m on mesophotic reefs.

The public comments did not provide any new or supplemental information on *Agaricia*'s distribution, habitat, and depth range. Supplemental information we found includes the following. Bongaerts *et al.* (2013) studied the depth distribution and genetic diversity of five agariciid species (*A. humilis*, *A. agaricites*, *A. lamarcki*, *A. grahamae*, and *Helioseris cucullata* [= *Leptoseris cucullata*]) and their symbiotic zooxanthellae in Curaçao. They found a distinct depth distribution among the species. *Agaricia humilis* and *A. agaricites* were more common at shallow depths, and *A. lamarcki*, *A. grahamae*, and *H. cucullata* were more common at deeper depths. They also found genetic segregation between coral host-symbiont communities at shallow and mesophotic depths.

##### Demographic Information

The SRR and SIR provided the following genus level information on *Agaricia*'s abundance and population trends: Coral specimens collected in 2010 from a mesophotic reef at Pulley Ridge, Florida suggest that corals, such as *Agaricia spp.*, that appear live in video images may actually be covered with algae rather than live coral tissue.

The public comments did not provide any new or supplemental information on *Agaricia*'s abundance or population trends. Supplemental information we found on *Agaricia*'s population trends includes the following: Stokes *et al.* (2010) reported a decrease in cover of *Agaricia spp.* in the Netherlands Antilles between 1982 and 2008 at all depths surveyed (10 to 30 m). An analysis of Caribbean monitoring data from 1970 to 2012 found that large, plating *Agaricia spp.* were one of the species groups that suffered the greatest proportional losses (Jackson *et al.*, 2014).

##### Other Biological Information

The SRR and SIR provided the following information on the life history of the genus *Agaricia*. In general, *Agaricia spp.* are gonochoric brooders. Several species such as *Agaricia agaricites*, *A. tenuifolia*, and *A. humilis* are known to use chemical cues from crustose coralline algae to mediate settlement.

The public comments did not provide new or supplemental information on the life history of the genus *Agaricia*. Supplemental information we found on *Agaricia*'s life history includes the following: *Agaricia spp.* can be one of the dominant taxonomic groups found in recruitment studies (Bak and Engel,

1979; Rogers *et al.*, 1984; Shearer and Coffroth, 2006).

##### Susceptibility to Threats

The SRR and SIR did not provide any genus level information on the susceptibility of *Agaricia* to ocean warming, and the public comments did not provide any new or supplemental information. Supplemental information we found on the susceptibility of the genus *Agaricia* to ocean warming includes the following: *Agaricia* is considered highly susceptible to bleaching. *Agaricia spp.* were the most susceptible to bleaching of the corals monitored during an unanticipated bleaching event at a remote, uninhabited island (Navassa), with higher bleaching prevalence at deeper sites (Miller *et al.*, 2011a). During the 1998 bleaching event in Belize, *A. tenuifolia*, a dominant coral, was nearly eradicated from the Channel Cay reef complex (Aronson *et al.*, 2002). During the 2005 bleaching event, nearly all *Agaricia spp.* were bleached at long-term monitoring sites in Buck Island National Monument, and they remained bleached comparatively longer than other species monitored (Clark *et al.*, 2009). Manzello *et al.* (2007) characterized *Agaricia* as having high susceptibility to bleaching in their study identifying bleaching indices and thresholds in the Florida Reef Tract, the Bahamas, and St. Croix, U.S. Virgin Islands. A long-term study in the Florida Keys found that bleaching prevalence was increased four to seven times by nutrient-enrichment in *Agaricia spp.*, the only genus that showed such a response (Vega Thurber *et al.*, 2014). This study indicated that the temperature threshold for bleaching may have been lowered by the nutrient enrichment. Notably, after removal of the nutrient enrichment, bleaching prevalence returned to background levels. Thus, we conclude that, absent species-specific information, species in the genus *Agaricia* should be considered highly susceptible to ocean warming-induced bleaching.

The SRR and SIR did not provide any genus level information on the susceptibility of *Agaricia* to disease, and the public comments did not provide any new or supplemental information. Supplemental information we found on the susceptibility of the genus *Agaricia* to disease includes the following. A study of coral diseases across the wider-Caribbean during the summer and fall of 2005 found the genus *Agaricia*, along with seven other major reef-building genera, to be particularly susceptible to coral diseases including white plague type II, Caribbean ciliate infection, and

to be infected with multiple diseases at the same time (Croquer and Weil, 2009). *Agaricia agaricites* decreased 87 percent in mean cover from the disease outbreak following the 2005 bleaching event in the U.S. Virgin Islands (Miller *et al.*, 2009). Thus, we conclude that, absent species-specific information, species in the genus *Agaricia* should be considered highly susceptible to diseases.

The SRR and SIR provided the following information on the susceptibility of *Agaricia* to acidification. No specific research has addressed the effects of acidification on the genus *Agaricia*. However, most corals studied have shown negative relationships between acidification and growth, and acidification is likely to contribute to reef destruction in the future. While ocean acidification has not been demonstrated to have caused appreciable declines in coral populations so far, it is considered a significant threat to corals by 2100.

The public comments did not provide any new or supplemental information on the susceptibility of *Agaricia* to acidification. Supplemental information we found on the susceptibility of the genus *Agaricia* to acidification includes the following. Crook *et al.* (2012) surveyed coral populations near submarine springs close to the Mesoamerican Reef in Mexico where water aragonite saturation state was naturally low due to groundwater seepage. *Agaricia* spp. were found near the springs, but only in waters with an aragonite saturation state greater than 2.5, indicating these species may be less tolerant than other coral species that were able to grow in under-saturated waters. Thus, we conclude that, absent species-specific information, species in the genus *Agaricia* should be considered to have some susceptibility to acidification.

The SRR and SIR provided genus level information on the susceptibility of *Agaricia* to sedimentation. The typically small calices of *Agaricia* spp. are not efficient at rejecting sediment, and species with horizontally-oriented plates or encrusting morphologies could be more sediment-susceptible than species with vertically-oriented plates as evidenced by fine sediment suspended in hurricanes that caused higher mortality in platy corals than hemispherical or non-flat ones. The public comments did not provide any new or supplemental information on the susceptibility of the genus *Agaricia* to sedimentation, and we did not find any new or supplemental information. Thus, we conclude that, absent species-specific information, species in the genus *Agaricia* should be considered to

have some susceptibility to sedimentation.

The SRR and SIR did not provide any genus level information on the susceptibility of *Agaricia* to nutrients, and the public comments did not provide any new or supplemental information. Supplemental information we found on the susceptibility of *Agaricia* spp. to nutrients includes the following. Treatment of *A. tenuifolia* with low (5 mg per l) and high (25 mg per l) doses of organic carbon resulted in 73 to 77 percent mortality, respectively, compared to 10 percent mortality of controls (Kuntz *et al.* 2005). Treatment of *A. tenuifolia* with nitrate (7.5  $\mu$ M), ammonium (25  $\mu$ M), and phosphate (2.5  $\mu$ M) caused about 50 percent mortality compared to 10 percent in controls (Kuntz *et al.* 2005). Thus, we conclude that, absent species-specific information, species in the genus *Agaricia* should be considered to have high susceptibility to nutrient enrichment based on this study in combination with the Vega Thurber *et al.* (2014) study that found increased bleaching in the presence of chronic nutrient enrichment.

The SRR and SIR did not provide any information on the susceptibility of *Agaricia* spp. to any other threats. The public comments did not provide any new or supplemental information, and we did not find any new or supplemental information on the susceptibility of *Agaricia* to any other threats.

#### Genus Conclusion

The studies cited above indicate that *Agaricia* spp. are highly susceptible to warming. In at least one location, a bleaching event resulted in 100 percent mortality of one *Agaricia* species. The genus also appears to be highly susceptible to diseases that can result in high rates of mortality and to be highly susceptible to impacts of nutrients. However, as described below, there is a fair amount of species-specific information for individual *Agaricia* species; therefore, we generally do not rely on the genus-level information to inform species level determinations. When necessary the appropriate inference is described in the species-specific information.

#### *Agaricia lamarcki*

##### Introduction

The SRR and SIR provided the following information on *A. lamarcki*'s morphology and taxonomy. *Agaricia lamarcki* has flat, unifacial, or encrusting plates that are commonly arranged in whorls. It is identifiable by

its morphology and the presence of white stars at the mouths. *Agaricia lamarcki* does not appear to have taxonomic problems.

The public comments did not provide new or supplemental information, and we did not find any new or supplemental information on *A. lamarcki*'s morphology or taxonomy.

##### Spatial Information

The SRR and SIR provided the following information on *A. lamarcki*'s distribution, habitat, and depth range. *Agaricia lamarcki* can be found in the western Atlantic off south Florida as far north as Palm Beach County, in the Gulf of Mexico including the Flower Garden Banks, and throughout the Caribbean including the Bahamas. *Agaricia lamarcki* is rare in shallow reef environments of 3 to 15 m, but is common at deeper depths of 20 to 100 m where it can be one of the dominant coral species. It is found in shaded or reduced light environments, on slopes and walls, and on mesophotic reefs in Curaçao, Florida, Jamaica, Puerto Rico, and the U.S. Virgin Islands.

The public comments did not provide new or supplemental information on *A. lamarcki*'s distribution, habitat, or depth range. Supplemental information we found on *A. lamarcki*'s distribution includes the following. Veron (2014) confirms the presence of *A. lamarcki* in seven out of 11 possible ecoregions in the western Atlantic and greater Caribbean that contain corals, and he strongly predicts the presence of *A. lamarcki* in the ecoregion surrounding the Flower Garden Banks based on published record or confirmed occurrence in surrounding ecoregions. The three ecoregions in which it is not reported are off the coasts of Bermuda, Brazil, and the southeast U.S. north of south Florida. We did not find any new or supplemental information on *A. lamarcki*'s habitat or depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. lamarcki*'s abundance and population trends. *Agaricia lamarcki* is reported as common. In the Netherlands Antilles, *A. lamarcki* increased in abundance or remained stable on reefs 30 to 40 m in depth from 1973 to 1992.

The public comments provided supplemental information on *A. lamarcki*'s abundance. Population estimates of *A. lamarcki* in the Florida Keys extrapolated from stratified random samples were  $3.1 \pm 1.3$  million (standard error (SE)) colonies in 2005 and  $0.2 \pm 0.2$  million colonies in 2012. No colonies were observed in 2009, but

fewer deep sites (>20 m) were surveyed in 2009 and 2012 compared to 2005. Most colonies observed were 20 to 30 cm in diameter, and partial mortality was highest (50 percent) in the largest size class (30 to 40 cm). *Agaricia lamarcki* ranked 35th in abundance out of 47 species in 2005 and 37th out of 40 species in 2012. In the Dry Tortugas, Florida, where more deep sites were surveyed, *A. lamarcki* ranked 12th out of 43 species in 2006, with population estimates extrapolated to  $14.3 \pm 2.6$  million colonies. It ranked 22nd out of 40 species in 2008 with population estimates extrapolated to  $2.1 \pm 0.5$  million colonies. Most of the colonies in 2006 were 10 to 30 cm in diameter, but colonies greater than 90 cm were observed. Partial mortality was highest in the 30 to 40 cm size class (approximately 35 percent) in 2006 and highest in the 20 to 30 cm size class (approximately 20 percent) in 2008. In 2008, most of the colonies were 0 to 10 cm in size, and the largest colonies observed were in the 50 to 60 cm size class (Miller *et al.*, 2013). Because population estimates were extrapolated from random samples, differences in population numbers between years are more likely a function of sampling effort rather than population trends over time. The public comments did not provide new or supplemental information on *A. lamarcki*'s population trends.

Supplemental information we found on *A. lamarcki*'s abundance and population trends includes the following. Between 1977 and 1987, colonies of *A. lamarcki* in monitored plots in Jamaica decreased from 34 to 31 colonies, indicating the net production by sexual and asexual means was not enough to compensate for mortality of the originally present colonies (Hughes, 1988). More than 40 percent of the colonies present in 1987 were derived from asexual fission of the original colonies present in 1977, and none of the six sexual recruits survived until the end of the study period (Hughes, 1988). In the U.S. Virgin Islands, *A. lamarcki* was the eleventh most common coral in terms of cover out of 55 species, and average cover across 18 monitoring sites was  $1.2 \pm 0.3$  (SE) percent in 2012 (Smith, 2013).

All information on *A. lamarcki*'s abundance and population trends can be summarized as follows. Based on population estimates, there are at least tens of millions of *A. lamarcki* colonies present in the Florida Keys and Dry Tortugas combined. Absolute abundance is higher than the estimate from these two locations given the presence of this species in many other locations throughout its range.

Population trends indicate this species may be declining in some areas, but because some of the trend data is lumped by genus or genus plus morphology, there is uncertainty that the trends represent *A. lamarcki* specifically. Thus, we conclude that *A. lamarcki* has likely declined in some areas and the population numbers at least in the tens of millions of colonies.

#### Other Biological Information

The SRR and SIR provided the following information on *A. lamarcki*'s life history. No information on the reproductive strategy of *A. lamarcki* is available, but congeners are gonochoric brooders. Larval settlement occurs primarily at deeper depths (26 to 37 m), but the species has also been found at shallower depths. Recruitment rates of *A. lamarcki* are low (*e.g.*, only one of 1,074 *Agaricia* recruits at the Flower Garden Banks may have been *A. lamarcki*), and net gains from sexual recruitment may be negligible at a decadal time scale. Population numbers may be maintained through asexual fission of larger colonies into smaller daughter colonies. Growth rates are slow; radial growth measurements from Jamaica ranged from zero to 1.4 cm per year and averaged approximately 0.5 cm per year. Growth rates are a bit slower, ranging from zero to 1.0 cm per year, at depths greater than 20 m. Maximum colony size is approximately two meters. *Agaricia lamarcki* is a relatively long-lived species, and individual colonies may persist for greater than a century. Based on monitoring in Jamaica, the half-life (mortality of half of monitored colonies) of *A. lamarcki* is 17 years. Mortality rates are size-specific (ranging from 10 to 25 percent), and partial mortality rates are high (ranging from 22 to 90 percent). Overall, demographic characteristics are low recruitment, high colony survival, and high partial mortality.

The public comments did not provide new or supplemental information on *A. lamarcki* life history. Supplemental information we found on *A. lamarcki* life history includes the following. Darling *et al.* (2012) performed a trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Agaricia lamarcki* was classified as a "weedy" species, thus likely more tolerant of environmental stress.

The SRR, SIR, and the public comments did not provide new or supplemental biological information for

*A. lamarcki*. Supplemental biological information we found about *A. lamarcki* includes the following. Out of five agariciid species sampled at a single reef in Curaçao, *A. lamarcki* was the only species that harbored multiple symbiont profiles across depth distribution; the other four species had only a single symbiont profile across depth. The symbiont community associated with *A. lamarcki* at 40 m depth was significantly different from those at both 10 m and 25 m (Bongaerts *et al.*, 2013).

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *A. lamarcki*'s vulnerabilities to threats as follows: Moderate vulnerability to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, and nutrients; and low vulnerability to sea level rise and collection and trade. No conclusions on *A. lamarcki*'s vulnerability to predation were made due to lack of available information on its susceptibility to this threat.

The SRR and SIR provided the following information on the susceptibility of *A. lamarcki* to ocean warming. *Agaricia lamarcki* is susceptible to bleaching from both high and low temperature anomalies. In laboratory studies, *A. lamarcki* had almost complete disruption of photosynthesis at 32 °C to 34 °C. Bleaching can be extensive; however, it may not result in mortality in *A. lamarcki*.

Van Woeseik *et al.* (2012) developed a coral resiliency index to evaluate extinction risk due to bleaching, based on biological traits and processes. Evaluations were performed at the genus level. They rated the resiliency of *Agaricia* as -2 out of a range of -6 to 7 observed in other coral genera. Less than or equal to -3 was considered highly vulnerable to extinction, and greater than or equal to 4 was considered highly tolerant. Thus, *Agaricia* was rated closer to the vulnerable end of the spectrum, though not highly vulnerable. This study was in the SIR, but the findings specific to *Agaricia* were not included. The public comments (comment 47) indicated the results of this study should be considered in the listing status of *A. lamarcki*.

The public comments did not provide any new or supplemental information on the susceptibility of *A. lamarcki* to ocean warming. Supplemental information we found on the susceptibility of *A. lamarcki* to ocean warming includes the following. During the 2005 bleaching event, greater than

80 percent of *A. lamarcki* colonies bleached at 12 sites in Puerto Rico (Waddell and Clarke, 2008). In the U.S. Virgin Islands, an average of 59 percent of *A. lamarcki* colonies (n = 11) bleached, and nine percent paled during the 2010 bleaching event (Smith *et al.*, 2013b). *Agaricia lamarcki* had high resistance to both hot and cold water anomalies that impacted the Florida Keys in 2005 and 2010, respectively, as indicated by their low tissue mortality compared to other coral species monitored (Lirman *et al.*, 2011).

All sources of information are used to describe *A. lamarcki*'s susceptibility to ocean warming as follows. *Agaricia lamarcki* has some susceptibility to ocean warming as evidenced by extensive bleaching during warm water temperature anomalies but observed low bleaching-related mortality. The available information does not support a more precise description of susceptibility.

The SRR and SIR did not provide any species-specific information on susceptibility of *A. lamarcki* to ocean acidification. The public comments did not provide new or supplemental information on the susceptibility of *A. lamarcki* to acidification, and we did not find any new or supplemental information.

All sources of information are used to describe *A. lamarcki*'s susceptibility to acidification as follows. There is uncertainty about how *A. lamarcki* will respond to ocean acidification, but there is genus-level evidence that *Agaricia* are not among the more tolerant species from areas of water with naturally lower aragonite saturation state. Thus, *A. lamarcki* likely has some susceptibility to ocean acidification, but the available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on *A. lamarcki*'s susceptibility to disease. White plague infections in *A. lamarcki* have been observed in Florida, Colombia, and St. Lucia, though no incidence of disease was observed in the Florida Keys in 1996 to 1998. Ciliate infections have been documented in *A. lamarcki*, and tumors may affect this species. The ecological and population impacts of disease have not been established for *A. lamarcki*.

The public comments did not provide any new or supplemental information on the susceptibility of *A. lamarcki* to disease, and we did not find any new or supplemental information on *A. lamarcki*'s susceptibility to disease.

All source of information are used to describe *A. lamarcki*'s susceptibility to disease as follows. *Agaricia lamarcki* is

susceptible to several diseases, including white plague, which has one of the fastest progression rates recorded in the Caribbean. However, there is no information on the population level effects of disease on *A. lamarcki* (e.g., rates of infection, percentage of population affected, and amounts of tissue loss). Genus-level information indicates high susceptibility to a disease outbreak following a bleaching event, indicating *A. lamarcki* is likely highly susceptible to disease.

The SIR and SRR did not provide any species-specific information on the trophic effects of fishing on *A. lamarcki*. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the trophic effects of fishing on *A. lamarcki*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. Thus, *A. lamarcki* likely has some susceptibility to the trophic effects of fishing because of low recruitment rates, though the available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on susceptibility of *A. lamarcki* to sedimentation. *Agaricia lamarcki* could be susceptible to sedimentation based on calix and colony morphology. This conclusion was based on genus-level information on susceptibility to sedimentation. The public comments did not provide new or supplemental information on the susceptibility of *A. lamarcki* to sedimentation, and we did not find new or supplemental information.

All sources of information are used to describe *A. lamarcki*'s susceptibility to sedimentation as follows. There is no species-specific information on the susceptibility of *A. lamarcki* to sedimentation. However, based on genus-level information, colony morphology and skeletal structure of *A. lamarcki* indicate it is likely poor at removing sediment. Thus, *A. lamarcki* likely has some susceptibility to sedimentation, but the available information does not support a more precise description of susceptibility.

The SRR and SIR did not provide any information on the susceptibility of *A. lamarcki* to nutrients, and the public comments did not provide any new or supplemental information. Supplemental information we gathered at the genus-level indicates that *A. lamarcki* is likely highly susceptible to nutrient enrichment.

The SRR and SIR did not provide species-specific information on the effects of sea level rise on *A. lamarcki*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *A. lamarcki*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *A. lamarcki* has some susceptibility to sea level rise, but the available information does not provide a more precise description of susceptibility.

The SRR and SIR provided the following information on the susceptibility of *A. lamarcki* to collection and trade. Only light trade has been recorded with gross exports averaging fewer than 10 pieces of coral annually between 2000 and 2005. The public comments did not provide new or supplemental information on the susceptibility of *A. lamarcki* to collection and trade. Supplemental information we found confirms that collection and trade of *A. lamarcki* remained low between 2000 and 2012 with gross exports averaging fewer than 10 pieces of coral annually (data available at <http://trade.cites.org/>). Thus, we conclude that *A. lamarcki* has low susceptibility to collection and trade.

The SRR and SIR provided the following information on the susceptibility of *A. lamarcki* to predation. Predation effects on *A. lamarcki* are unknown. The public comments did not provide any new or supplemental information, and we did not find any new or supplemental information on the susceptibility of *A. lamarcki* to predation. We conclude that while *A. lamarcki* likely has some susceptibility to predation, available information is lacking, and we cannot say whether it is a threat.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. lamarcki*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *Agaricia lamarcki* occurs in eight Atlantic ecoregions that encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua &

Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Overseas Territories), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *A. lamarcki*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as a percentage of those countries and kingdoms whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *A. lamarcki* are reef fishing regulations and area management for protection and conservation. However, half of the reef fishing regulations are limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *A. lamarcki*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the extinction risk for *A. lamarcki* include the widespread decline in environmental conditions in the Caribbean, potential losses to disease, severe effects of bleaching, and limited sediment tolerance. Factors that reduce extinction risk include occurrence primarily at great depth, where disturbance events are less frequent, and life history characteristics that have allowed the species to remain relatively persistent compared to other deep corals despite low rates of sexual recruitment.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our

knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. lamarcki*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Although it is geographically located in the heavily disturbed Caribbean, *A. lamarcki*'s predominant occurrence at depths of 20 to 100 m reduces its exposure to disturbance events that have resulted in the decreased resilience of reefs in the Caribbean and moderates vulnerability to extinction over the foreseeable future. *Agaricia lamarcki*'s life history characteristics of large colony size and long life span have enabled it to remain relatively persistent despite slow growth and low recruitment rates, thus moderating vulnerability to extinction. Although we concluded that *A. lamarcki* is likely highly susceptible to disease, population level effects of disease have not been documented in *A. lamarcki* thus far, indicating the currently low vulnerability to extinction from this threat. Additionally, although *A. lamarcki* has been observed to have high levels of warming-induced bleaching, bleaching-related mortality appears to be low, indicating that vulnerability to extinction from ocean warming is currently low. Deeper areas of *A. lamarcki*'s range will usually have lower temperatures than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. *Agaricia lamarcki*'s habitat includes shaded or reduced light environments, slopes, walls, and mesophotic reefs. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. *Agaricia lamarcki*'s absolute abundance has been estimated as at

least tens of millions of colonies in the Florida Keys and Dry Tortugas combined and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. Its abundance, life history characteristics, and depth distribution, combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. lamarcki* was proposed for listing as threatened because of: Moderate vulnerability to ocean warming (E), disease (C), and acidification (E); low relative recruitment rate (E); moderate overall distribution (based on narrow geographic distribution and wide depth distribution (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. lamarcki* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. lamarcki*'s spatial structure, demography, threat susceptibilities, and management none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time because:

(1) *Agaricia lamarcki*'s predominant occurrence at depths of 20 to 100 m in heterogeneous habitats, including shaded or reduced light environments, on slopes and walls, and on mesophotic reefs, throughout the Caribbean basin reduces exposure to any given threat event or adverse condition that does not occur uniformly throughout the species' range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Agaricia lamarcki*'s absolute abundance is at least tens of millions of colonies based on estimates from two locations. Absolute abundance is higher than estimates from these locations since *it* occurs in many other locations throughout its range. This provides buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity, and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, *A. lamarcki* is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. lamarcki* is not warranted for listing at this time under any of the listing factors, and we withdraw our proposal to list the species as threatened.

#### Genus *Mycetophyllia*

There are five species in the genus *Mycetophyllia* that all occur in the western Atlantic and Caribbean (Veron, 2000). Most species of *Mycetophyllia* can be difficult to distinguish in the field, and many studies report data to the genus level rather than species. Therefore, all information reported for the genus appears in this section, and information reported specifically for *M. ferox* is presented in the species section.

#### Demographic Information

The SRR, SIR, and the public comments did not provide information on *Mycetophyllia* abundance or population trends. Supplemental

information we found on *Mycetophyllia*'s abundance and population trends includes the following. Percent cover of *Mycetophyllia* spp. between 2001 and 2006 was less than approximately 0.02 percent on St. John (233 sites surveyed) and St. Croix (768 sites surveyed), U.S. Virgin Islands and La Parguera, Puerto Rico (Waddell and Clarke, 2008). Similarly, cover of *Mycetophyllia* spp. on the mesophotic Hind Bank in the U.S. Virgin Islands was  $0.02 \pm 0.01$  percent in 2007 (Smith *et al.*, 2010). Cover of *Mycetophyllia* spp. was 0.1 percent between 2002 and 2004 on four islands in the Bahamas Archipelago (Roff *et al.*, 2011). Between 2005 and 2007, *Mycetophyllia* spp. comprised 0.1 percent or less of the coral cover and occurred in densities of 1.0 colony per 10 m<sup>2</sup> in parts of southeast Florida and the Florida Keys (Wagner *et al.*, 2010). In Roatan, Honduras, *Mycetophyllia* sp. cover in permanent photo-stations increased between 1996 and 1998 from 0.57 percent to 0.77 percent but subsequently decreased to 0.26 percent in 2003 and 0.15 percent in 2005 (Riegl *et al.*, 2009).

#### Susceptibility to Threats

The SRR, SIR, and public comments did not provide information on *Mycetophyllia*'s susceptibility to threats. Supplemental information we found on *Mycetophyllia*'s susceptibility to ocean warming includes the following. During the 1995 bleaching event in Belize, 24 percent of 21 colonies monitored *Mycetophyllia* bleached (McField, 1999). In Roatan, Honduras, 11 percent [sic] of 10 monitored *Mycetophyllia* sp. colonies bleached and 11 percent [sic] partially bleached during the 1998 bleaching event; mortality of *Mycetophyllia* colonies was 11 percent (Riegl *et al.*, 2009).

Bleaching of *Mycetophyllia* was 62 percent across all 28 locations surveyed in Puerto Rico during the 2005 temperature anomaly (Waddell and Clarke, 2008). Additionally, a post-bleaching outbreak of white plague resulted in a massive collapse of *Mycetophyllia* colonies at most reefs on the east, south, and west coasts of Puerto Rico and reproductive failure during the 2006 mass spawning (Waddell and Clarke, 2008). Off Mona and Desecheo Islands, Puerto Rico in 2005, paling occurred in 65 percent of *Mycetophyllia* colonies, and bleaching occurred in 10 percent (Bruckner and Hill, 2009).

In surveys conducted between August and October 2005 to 2009 from the lower Florida Keys to Martin County, average mortality of *Mycetophyllia* spp.

was  $0.6 \pm 6.4$  percent, which was the eighth highest out of 25 of the most abundant species (Lirman *et al.*, 2011). During the 2010 cold-water event, average mortality of *Mycetophyllia* spp. across 76 sites from the lower Florida Keys to Martin County was  $15.0 \pm 28.3$  percent, which was the eleventh highest of the 25 most abundant species (Lirman *et al.*, 2011).

During the 2005 bleaching event, *Mycetophyllia* spp. were among the most severely affected of 22 coral species reported to have bleached across 91 of 94 sites in northeast St. Croix, U.S. Virgin Islands (Wilkinson and Souter, 2008). In the U.S. Virgin Islands, the one colony of *Mycetophyllia* sp. observed at 18 sites, bleached during 2005. Six colonies were subsequently monitored after the 2010 mild bleaching event with average of eight percent bleaching (Smith *et al.*, 2013b).

Supplemental information we found on the susceptibility of *Mycetophyllia* to disease includes the following. White plague (Nugues, 2002) and red band disease (Waddell, 2005) have been reported to infect *Mycetophyllia* species. In 2004, prevalence of disease in *Mycetophyllia* was approximately two to three percent in Mexico (Harvell *et al.*, 2007).

#### *Mycetophyllia ferox*

##### Introduction

The SRR and SIR provided the following information on *M. ferox*'s morphology and taxonomy. *Mycetophyllia ferox* forms a thin, encrusting plate that is weakly attached. *Mycetophyllia ferox* is taxonomically distinct. Maximum colony size is 50 cm.

Public comments did not provide new or supplemental information on *M. ferox*'s taxonomy or morphology. Supplemental information we found on *M. ferox*'s taxonomy and morphology includes the following. Zlatarski and Estalella (1982) reported 14 out of 25 *Mycetophyllia* colonies collected from Cuba were intermediate between *M. ferox*, and *M. lamarkiana*, and parts of two colonies were comparable to *M. ferox* or *M. lamarkiana*, illustrating potential morphological plasticity between species.

##### Spatial Information

The SRR and SIR provided the following information on *M. ferox*'s distribution, habitat, and depth range. *Mycetophyllia ferox* occurs in the western Atlantic and throughout the wider Caribbean. It has not been reported in the Flower Garden Banks (Gulf of Mexico) or in Bermuda. It has been reported in reef environments in

water depths of 5 to 90 m, including shallow and mesophotic habitats.

The public comments did not provide new or supplemental information on *M. ferox*'s distribution, habitat, or depth range. Supplemental information we found on *M. ferox*'s distribution includes the following. Veron (2014) confirms the occurrence of *M. ferox* in seven out of a possible 11 ecoregions in the Caribbean and western Atlantic that contain corals. The four ecoregions where it is not reported are the Flower Garden Banks, off the coasts of Bermuda, Brazil, and the southeast U.S. north of south Florida. We did not find any supplemental information on *M. ferox*'s habitat or depth range.

#### Demographic Information

The SRR and SIR provided the following information on *M. ferox*'s abundance and population trends. *Mycetophyllia ferox* is usually uncommon or rare, constituting less than 0.1 percent of all coral species at generally less than one percent of the benthic cover. Density of *M. ferox* in southeast Florida and the Florida Keys was approximately 0.8 colonies per 10 m<sup>2</sup> between 2005 and 2007. There is indication that the species was much more abundant in the upper Florida Keys in the 1970s. In a survey of 97 stations in the Florida Keys, *M. ferox* declined in occurrence from 20 stations in 1996 to four stations in 2009. At 21 stations in the Dry Tortugas, *M. ferox* declined in occurrence from eight stations in 2004 to three stations in 2009.

The public comments provided the following supplemental information on *M. ferox*'s abundance. In stratified random surveys in the Florida Keys, *M. ferox* ranked 39th most abundant out of 47 in 2005, 43rd out of 43 in 2009, and 40th out of 40 in 2012. Extrapolated population estimates were  $1.0 \pm 0.7$  (SE) million in 2005,  $9,500 \pm 9,500$  (SE) colonies in 2009, and  $7,000 \pm 7,000$  (SE) in 2012. These abundance estimates are based on random surveys, and differences between years are more likely a result of sampling effort rather than population trends. The most abundant size class was 10 to 20 cm diameter that equaled the combined abundance of the other size classes. The largest size class was 30 to 40 cm. Average partial mortality per size class ranged from nearly 0 to 50 percent and was greatest in the 20 to 30 cm size class (Miller *et al.*, 2013).

In the Dry Tortugas, Florida, *M. ferox* ranked 35th most abundant out of 43 species in 2006 and 30th out of 40 in 2008. Population estimates were  $0.5 \pm 0.4$  (SE) million in 2006 and  $0.5 \pm 0.2$

million (SE) in 2008. The number of colonies in 2006 was similar between the 0 to 10 cm and 10 to 20 cm size classes, and the largest colonies were in the 20 to 30 cm size class. Greatest partial mortality was around 10 percent. Two years later, in 2008, the highest proportion of colonies was in the 20 to 30 cm size class, and the largest colonies were in the 40 to 50 cm size class. The greatest partial mortality was about 60 percent in the 30 to 40 cm size class, however the number of colonies at that size were few (Miller *et al.*, 2013).

Supplemental information we found on *M. ferox*'s abundance and population trends confirms *M. ferox*'s low percent cover, encounter rate, and density. In a survey of Utila, Honduras between 1999 and 2000, *M. ferox* was observed at eight percent of 784 surveyed sites and was the 36th most commonly observed out of 46 coral species; other *Mycetophyllia* species were seen more commonly (Afzal *et al.*, 2001). In surveys of remote southwest reefs of Cuba, *M. ferox* was observed at one of 38 reef-front sites, with average abundance was  $0.004 \pm 0.027$  (standard deviation (SD)) colonies per 10 m transect; this was comparatively lower than the other three *Mycetophyllia* species observed (Alcolado *et al.*, 2010). Between 1998 and 2004, cover of *M. ferox* ranged between 0.3 and 0.4 percent in three of six sites monitored in Colombia (Rodriguez-Ramirez *et al.*, 2010). In Barbados, *M. ferox* was observed on one of seven reefs surveyed, and the average cover was 0.04 percent (Tomascik and Sander, 1987).

Benthic cover of *M. ferox* in the Red Hind Marine Conservation District off St. Thomas, U.S. Virgin Islands, which includes mesophotic coral reefs, was  $0.003 \pm 0.004$  percent in 2007, accounting for 0.02 percent of coral cover, and ranking 20th highest in cover out of 21 coral species (Nemeth *et al.*, 2008; Smith *et al.*, 2010). In the U.S. Virgin Islands between 2001 and 2012, cover of *M. ferox* appeared in 12 of 33 survey sites and accounted for 0.01 percent of the benthos, and 0.07 percent of the coral cover, ranking as 13th most common (Smith, 2013).

In 1981, *M. ferox* was observed on one of four reefs surveyed in the upper Florida Keys at 0.1 percent cover (Burns, 1985). In surveys of the Florida Keys between 1996 and 2003, cover of *M. ferox* was 0.022, 0.005, and less than 0.001 percent on patch reefs, deep offshore reefs, and shallow offshore reefs, respectively (Somerfield *et al.*, 2008). At permanent monitoring stations in the Florida Keys, the number of stations where *M. ferox* was present declined between 1996 and 2003

(Waddell, 2005). Between 2005 and 2010, *M. ferox* was one of 42 species surveyed and was found the least abundant being observed at densities of 0.02 and 0.01 colonies per 10 m<sup>2</sup> on mid-channel reefs and fore-reefs, respectively, on the Florida reef tract (Burman *et al.*, 2012).

All information on *M. ferox*'s abundance and population trends can be summarized as follows. *Mycetophyllia ferox* has been reported to occur on 3 to 50 percent of reefs surveyed and is one of the least common coral species observed. On reefs where *M. ferox* is found, it generally occurs at abundances of less than one colony per 10 m<sup>2</sup> and percent cover of less than 0.1 percent. Based on population estimates, there are at least hundreds of thousands of *M. ferox* colonies present in the Florida Keys and Dry Tortugas combined. Absolute abundance is higher than the estimate from these two locations given the presence of this species in many other locations throughout its range. Low encounter rate and percent cover coupled with the tendency to include *Mycetophyllia* spp. at the genus level make it difficult to discern population trends of *M. ferox* from monitoring data. However, reported losses of *M. ferox* from monitoring stations in the Florida Keys and Dry Tortugas (63 to 80 percent loss) indicate population decline in these locations. Based on declines in Florida, we conclude *M. ferox* has likely declined throughout its range.

#### Other Biological Information

The SRR and SIR provided the following information on *M. ferox*'s life history. *Mycetophyllia ferox* is a hermaphroditic brooding species. Colony size at first reproduction is greater than 100 cm<sup>2</sup>. Recruitment of *M. ferox* appears to be very low, even in studies from the 1970s.

The public comments did not provide new or supplemental information on *M. ferox*'s life history. Supplemental information we found on *M. ferox*'s life history includes the following. *Mycetophyllia ferox* has a lower fecundity compared to *M. aliciae*, *M. lamarckiana* and *M. danaana* (Morales Tirado, 2006). Over a 10 year period, no colonies of *M. ferox* were observed to recruit to an anchor-damaged site in the U.S. Virgin Islands although adults were observed on the adjacent reef (Rogers and Garrison, 2001). Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. *Mycetophyllia ferox* was classified as a

“weedy” species, thus likely more tolerant of environmental stress.

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *M. ferox*'s vulnerabilities to threats as follows: High vulnerability to disease and nutrient enrichment; moderate vulnerability to ocean warming, acidification, trophic effects of fishing, and sedimentation; and low vulnerability to sea level rise, predation, and collection and trade.

The SRR and SIR provided the following information on *M. ferox*'s susceptibility to ocean warming. No bleached *M. ferox* colonies were observed in Florida or Barbados in a wide-scale survey during the 2005 mass-bleaching event, although the number of colonies was small.

The public comments did not provide new or supplemental information on the susceptibility of *M. ferox* to ocean warming. Supplemental information we found on the susceptibility of *M. ferox* to ocean warming includes the following. In surveys of the lower Florida Keys and Dry Tortugas during the 1998 bleaching event, approximately 20 percent of *M. ferox* colonies bleached; out of the 14 species reported to have experienced bleaching of at least 50 percent of the colony, *M. ferox* was one of the least affected (Waddell, 2005). Approximately 50 percent of *M. ferox* colonies bleached at 12 locations in Puerto Rico during the 2005 bleaching event (Waddell and Clarke, 2008). During the 2005 Caribbean bleaching event, neither of the two colonies of *M. ferox* monitored at six sites in Barbados bleached; an average of 71 percent of all coral colonies bleached at those six sites during the event (Oxenford *et al.*, 2008).

All sources of information are used to describe *M. ferox*'s susceptibility to ocean warming as follows. The bleaching reports available specifically for *M. ferox* and at the genus level indicate similar trends of relatively low bleaching observed in 1995, 1998, and 2010 (less than 25 percent) and higher levels (50 to 65) or no bleaching in the more severe 2005 bleaching event. Reproductive failure and a disease outbreak were reported for the genus after the 2005 bleaching event. Although bleaching of most coral species is spatially and temporally variable, understanding the susceptibility of *M. ferox* is somewhat confounded by the species' low sample size in any given survey due to its low encounter rate. We conclude that *M. ferox* has some susceptibility to ocean warming.

However, the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR provided the following information on the susceptibility of *M. ferox* to acidification. No specific research has addressed the effects of acidification on the genus *Mycetophyllia*. However, most corals studied have shown negative relationships between acidification and growth, and acidification is likely to contribute to reef destruction in the future. While ocean acidification has not been demonstrated to have caused appreciable declines in coral populations to date, it is considered to become a significant threat to corals by 2100.

The public comments did not provide new or supplemental information on the susceptibility of *M. ferox* to acidification, and we did not find any new or supplemental information.

All sources of information are used to describe *M. ferox*'s susceptibility to acidification as follows. There is uncertainty about how *M. ferox* will respond to ocean acidification. Based on the negative effects of acidification on growth of most corals, *M. ferox* likely has some susceptibility to acidification. The available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on *M. ferox*'s susceptibility to disease. *Mycetophyllia ferox* is susceptible to white plague. Diseased *M. ferox* colonies were reported in the upper Florida Keys in the mid-1970s; between 24 and 73 percent of *M. ferox* colonies were infected per site. At one reef site, 20 to 30 percent of the *M. ferox* colonies died from disease during a one-year period.

The public comments did not provide new or supplemental information on the susceptibility of *M. ferox* to disease. Supplemental information we found on the susceptibility of *M. ferox* to disease includes the following. Porter *et al.* (2001) report the loss of *M. ferox* from many of the permanent monitoring stations (160 stations at 40 sites) in the Florida Keys between 1996 and 1998 due to coral disease.

All sources of information are used to describe *M. ferox*'s susceptibility to disease as follows. From reports in the Florida Keys, *M. ferox* appears to be highly susceptible to disease, specifically white plague, and reports of high losses and correlation with higher temperatures date back to the mid-1970s (Dustan, 1977). Although heavy impacts of disease on *M. ferox* have not been reported in other locations, an outbreak of white plague was credited with

causing heavy mortality at the genus level in Puerto Rico after the 2005 bleaching event. We conclude that the susceptibility of *M. ferox* to disease is high.

The SIR and SRR did not provide any species-specific information on the trophic effects of fishing on *M. ferox*. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the trophic effects of fishing on *M. ferox*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. Thus, *M. ferox* likely has some susceptibility to the trophic effects of fishing given its low recruitment rates. The available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on the susceptibility of *M. ferox* to nutrient enrichment. *Mycetophyllia ferox* appeared to be absent at fringing reef sites in Barbados impacted by sewage pollution.

The public comments did not provide any new or supplemental information on the susceptibility of *M. ferox* to nutrient enrichment, and we did not find any new or supplemental information.

All sources of information are used to describe *M. ferox*'s susceptibility to nutrient enrichment as follows. *Mycetophyllia ferox* may be susceptible to nutrient enrichment as evidenced by its absence from eutrophic sites in one location. However, there is uncertainty about whether the absence is a result of eutrophic conditions or a result of uncommon or rare occurrence. Therefore, we conclude that *M. ferox* likely has some susceptibility to nutrient enrichment. However, the available information does not support a more precise description of susceptibility.

The SRR and SIR did not provide any species or genus information on the susceptibility of *M. ferox* to sedimentation but provided the following. Land-based sources of pollution (including sediment) often act in concert rather than individually and are influenced by other biological (*e.g.*, herbivory) and hydrological factors. Collectively, land-based sources of pollution are unlikely to produce extinction at a global scale; however, they may pose significant threats at local scales and reduce the resilience of corals to bleaching.

The public comments did not provide new or supplemental information on the

susceptibility of *M. ferox* to sedimentation, and we did not find any new or supplemental information. We conclude that *M. ferox* has some level of susceptibility to sedimentation, but the available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on the susceptibility of *M. ferox* to predation. *Mycetophyllia ferox* has not been susceptible to predation. Public comments did not provide new or supplemental information on *M. ferox*'s susceptibility to predation, and we did not find any new or supplemental information. We conclude that *M. ferox* has low susceptibility to predation.

The SRR and SIR did not provide species-specific information on the effects of sea level rise on *M. ferox*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *M. ferox*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *M. ferox* has some susceptibility to sea level rise, but the available information does not provide a more precise description of susceptibility.

The SRR and SIR provided the following information on *M. ferox*'s susceptibility to collection and trade. *Mycetophyllia ferox* is not reported to be an important species for trade. Exports of *M. ferox* were ten pieces in 2000, two in 2003, and five in 2007.

The public comments did not provide new or supplemental information on the susceptibility of *M. ferox* to collection and trade. Supplemental information we found confirmed low collection and trade of *M. ferox* with gross exports between 2000 and 2012 averaging fewer than two corals per year (data available at <http://trade.cites.org/>). Thus, we conclude that *M. ferox* has low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *M. ferox*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *M. ferox* occurs in seven Atlantic ecoregions that

encompass 26 kingdom's or countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Honduras, Jamaica, Kingdom of the Netherlands, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Overseas Territories), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *M. ferox*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as the percentages of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: general coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *M. ferox* are reef fishing regulations and area management for protection and conservation. However, half of the reef-fish fishing regulations are limited in scope and may not provide substantial protection for the coral species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *M. ferox*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the extinction risk for *M. ferox* include disease, rare abundance, and observed declines in abundance.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the

species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. ferox*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. *Mycetophyllia ferox* has declined due to disease in at least a portion of its range and has low recruitment, which limits its capacity for recovery from mortality events and exacerbates vulnerability to extinction. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *M. ferox* is limited to an area with high, localized human impacts and predicted increasing threats. Its depth range of five to 90 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower temperatures than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes shallow and mesophotic reefs which moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. *Mycetophyllia ferox* is usually uncommon to rare throughout its range. Its absolute abundance has been estimated as at least hundreds of thousands of colonies in the Florida Keys and Dry Tortugas combined and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. Its abundance, combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the threats are non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *M. ferox* was proposed for listing as endangered because of: High

vulnerability to disease (C); moderate vulnerability to ocean warming (E) and acidification (E); high vulnerability to nutrient over-enrichment (A and E); rare general range-wide abundance (E); decreasing trend in abundance (E); low relative recruitment rate (E); moderate overall distribution (based on narrow geographic distribution and wide depth distribution (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. ferox* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of the buffering capacity of this species' spatial and demographic traits, and the best available information above on *M. ferox*'s spatial structure, demography, threat susceptibilities, and management. This combination of factors indicates that *M. ferox* is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Mycetophyllia ferox* is highly susceptible to disease (C) and susceptible to ocean warming (ESA Factor E), acidification (E), trophic effects of fishing (A), nutrients (A, E), and sedimentation (A, E). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address global threats (D);

(2) *Mycetophyllia ferox* has experienced significant declines in Florida and has likely experienced decline in other locations in its range;

(3) *Mycetophyllia ferox* has a usually uncommon to rare occurrence throughout its range, which heightens the potential effect of localized mortality events and leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections;

(4) *Mycetophyllia ferox* is geographically located in the highly disturbed Caribbean where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(5) *Mycetophyllia ferox*'s low recruitment limits the capacity for recovery from threat-induced mortality events throughout the range over the foreseeable future.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *M. ferox*'s spatial structure, demography, threat vulnerabilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *Mycetophyllia ferox*'s distribution within the Caribbean increases its risk of exposure to threats as described above, its depth distribution is five to 90 m and its habitat includes various shallow and mesophotic reef environments. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) *Mycetophyllia ferox*'s absolute abundance is at least hundreds of thousands of colonies based on estimates from two locations. Absolute abundance is higher than estimates from these locations since *M. ferox* occurs in many other locations throughout its range. This absolute abundance allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. Its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does

not warrant listing as endangered at this time.

Range-wide, multitudes of conservation efforts are already broadly employed that are likely benefiting *M. ferox*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

#### Genus *Dendrogyra*

The SRR and SIR provided the following information on morphology and taxonomy of *Dendrogyra*. *Dendrogyra cylindrus* is the only species in the genus *Dendrogyra*. It is easily identifiable, and there is no taxonomic confusion. The public comments did not provide new or supplemental information on the morphology or taxonomy of *D. cylindrus*, and we did not find any new or supplemental information.

#### *Dendrogyra cylindrus*

##### Introduction

The SRR and SIR provided the following information on the morphology of *D. cylindrus*. *Dendrogyra cylindrus* forms cylindrical columns on top of encrusting bases. Colonies are generally grey-brown in color and may reach three meters in height. Tentacles remain extended during the day, giving columns a furry appearance.

##### Spatial Information

The SRR and SIR provided the following information on *D. cylindrus*'s distribution, habitat, and depth range. *Dendrogyra cylindrus* is present in the western Atlantic and throughout the greater Caribbean. The SRR reports a single known colony in Bermuda that is in poor condition. *Dendrogyra cylindrus* inhabits most reef environments in water depths ranging from one to 25 m.

The public comments did not provide new or supplemental information on *D. cylindrus*'s distribution, habitat, or depth range. Supplemental information we found on *D. cylindrus*'s distribution, habitat, and depth range include the following. *Dendrogyra cylindrus* is absent from the southwest Gulf of Mexico (Tunnell, 1988). There is fossil evidence of the presence of *D. cylindrus* off Panama less than 1000 years ago, but it has been reported as absent today (Florida Fish and Wildlife Conservation Commission, 2013). Veron (2014)

confirms the presence of *D. cylindrus* in seven out of a potential 11 ecoregions in the western Atlantic and wider-Caribbean that are known to contain corals. The four ecoregions in which it is not reported are the Flower Garden Banks and off the coasts of Bermuda, Brazil, and the southeast U.S. north of south Florida. Although *D. cylindrus*'s depth range is 1 to 25 m, it is most common between five and 15 m depth (Acosta and Acevedo, 2006; Cairns, 1982; Goreau and Wells, 1967).

All information on *D. cylindrus*'s distribution can be summarized as follows. *Dendrogyra cylindrus* is distributed throughout most of the greater Caribbean in most reef environments between 1 to 25 m depth. It currently appears to be absent from Panama where it historically occurred within the last 1000 years.

#### Demographic Information

The SRR and SIR provided the following information on *D. cylindrus*'s abundance and population trends. *Dendrogyra cylindrus* is uncommon but conspicuous with scattered, isolated colonies. It is rarely found in aggregations. *Dendrogyra cylindrus* has been reported to be common on Pleistocene reefs around Grand Cayman, but rare on modern reefs. In monitoring studies, cover is generally less than one percent. Between 2005 and 2007, mean density of *D. cylindrus* was approximately 0.5 colonies per 10 m<sup>2</sup> in the Florida Keys. In a study of *D. cylindrus* demographics at Providencia Island, Colombia, a total of 283 *D. cylindrus* colonies were detected in a survey of 1.66 km<sup>2</sup> for an overall density of 172.0 ± 177.0 (SE) colonies per km<sup>2</sup>.

The public comments provided supplemental information on *D. cylindrus*'s abundance but not on population trends. In stratified random samples of the Florida Keys, *D. cylindrus* ranked least common out of 47 coral species in 2005 and 41 out of 43 species in 2009. Based on random surveys stratified by habitat type, extrapolated abundance for the Florida Keys was 23,000 ± 23,000 (SE) colonies in 2005 and 25,000 ± 25,000 (SE) colonies in 2009. Because these population estimates were based on random sampling, differences between years is more likely a function of sampling effort rather than an indication of population trends. All *D. cylindrus* colonies reported in 2005 were in the 70 to 80 cm diameter size class with less than two percent partial mortality. Four years later in 2009, all reported colonies were greater than 90 cm. No *D. cylindrus* colonies were encountered in

600 surveys from Key Biscayne to Key West, Florida in 2012, with the authors noting sampling design was not optimized for this species. This species was not reported in the Dry Tortugas in 2006 and 2008, and rarely encountered during pilot studies conducted over several years (1999 to 2002) ranking 49th out of 49 coral species (Miller *et al.*, 2013).

Supplemental information we found on *D. cylindrus*'s abundance and population trends confirms the uncommon occurrence, rare encounter rate, low percent cover, and low density. During surveys of Utila, Honduras between 1999 and 2000, *D. cylindrus* was sighted in 19.6 percent of 784 surveys and ranked 26th most common in abundance out of 48 coral species (Afzal *et al.*, 2001). In surveys of the upper Florida Keys in 2011, *D. cylindrus* was the second rarest out of 37 coral species and encountered at one percent of sites (Miller *et al.*, 2011b).

In stratified random surveys from Palm Beach County to the Dry Tortugas, Florida between 2005 and 2010, *D. cylindrus* was seen only on the ridge complex and mid-channel reefs at densities of 1.09 and 0.1 colonies per 10 m<sup>2</sup>, respectively (Burman *et al.*, 2012). Average number of *D. cylindrus* colonies in remote reefs off southwest Cuba was 0.013 ± 0.045 colonies per 10 m transect, and the species ranked sixth rarest out of 38 coral species (Alcolado *et al.*, 2010).

Out of 283 *D. cylindrus* colonies at Providencia Island, Colombia, 70 were fragments resulting from asexual fragmentation, and no sexual recruits were observed. Size class distribution was skewed to smaller size classes less than 60 cm in height, and average colony height was 73.8 ± 46.0 cm (Acosta and Acevedo, 2006).

*Dendrogyra cylindrus*'s average percent cover was 0.002 on patch reefs and 0.303 in shallow offshore reefs in annual surveys of 37 sites in the Florida Keys between 1996 and 2003 (Somerfield *et al.*, 2008). At permanent monitoring stations in the U.S. Virgin Islands, *D. cylindrus* has been observed in low abundance at 10 of 33 sites and, where present, ranged in cover from less than 0.05 percent to 0.22 percent (Smith, 2013). In Dominica, *D. cylindrus* comprised less than 0.9 percent cover and was present at 13.3 percent of 31 surveyed sites (Steiner, 2003). At seven fringing reefs off Barbados, *D. cylindrus* was observed on one reef, and cover was 2.7 ± 1.4 percent (Tomascik and Sander, 1987). In monitored photo-stations in Roatan, Honduras, cover of *D. cylindrus* increased slightly from 1.35 percent in 1996 to 1.67 percent in 1999 and then

declined to 0.44 percent in 2003 and 0.43 percent in 2005 (Riegl *et al.*, 2009). In the U.S. Virgin Islands, seven percent of 26 monitored colonies experienced total colony mortality between 2005 and 2007, though the very low cover of *D. cylindrus* (0.04 percent) remained relatively stable during this time period (Smith *et al.*, 2013b).

All sources of information on *D. cylindrus*'s abundance and population trends can be summarized as follows. Based on population estimates, there are at least tens of thousands of *D. cylindrus* colonies present in the Florida Keys. Absolute abundance is higher than the estimate from this location given the presence of this species in many other locations throughout its range. Although there is evidence of potentially higher population levels in some areas of the Caribbean during the Pleistocene, *D. cylindrus* is currently uncommon to rare. Few studies report *D. cylindrus* population trends, and the low abundance and infrequent encounter rate in monitoring programs result in small samples sizes. The low coral cover of this species renders monitoring data difficult to extrapolate to realize trends. Therefore, we conclude that *D. cylindrus* is naturally uncommon to rare and that trends are unknown.

#### Other Biological Information

The SRR and SIR provided the following information on *D. cylindrus*'s life history. *Dendrogyra cylindrus* is a gonochoric (separate sexes) broadcast spawning species with relatively low annual egg production for its size. The combination of gonochoric spawning with persistently low population densities is expected to yield low rates of successful fertilization and low larval supply. Sexual recruitment of this species is low, and reported juvenile colonies in the Caribbean are lacking. *Dendrogyra cylindrus* can propagate by fragmentation following storms or other physical disturbance. Average growth rates of 1.8 to 2.0 cm per year in linear extension have been reported in the Florida Keys compared to 0.8 cm per year in Colombia and Curaçao. Partial mortality rates are size-specific with larger colonies having greater rates. Frequency of partial mortality can be high (65 percent of 185 colonies surveyed in Colombia), while the amount of partial mortality per colony is generally low (average of 3 percent of tissue area affected per colony).

The public comments did not provide new or supplemental information on *D. cylindrus*'s life history. Supplemental information we found on *D. cylindrus*'s life history includes the following. Spawning observations have been made

several nights after the full moon of August in the Florida Keys (Neely *et al.*, 2013; Waddell and Clarke, 2008).

Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Dendrogyra cylindrus* was classified as a “competitive” species, thus likely more vulnerable to environmental stress.

The SRR and SIR provided the following other biological information for *D. cylindrus*. *Dendrogyra cylindrus* appears to be sensitive to cold temperatures. Feeding rates (removal of suspended particles in seawater) are low relative to most other Caribbean corals, indicating it is primarily a tentacle feeder rather than a suspension feeder. However, *D. cylindrus* has a relatively high photosynthetic rate, and stable isotope values suggest it receives substantial amounts of photosynthetic products from its zooxanthellae.

The public comments did not provide new or supplemental biological information for *D. cylindrus*. Supplemental information we found confirms that *D. cylindrus* is sensitive to cold temperatures and is summarized as follows. In laboratory studies of cold shock, *D. cylindrus* had the highest zooxanthellae expulsion rate of three species tested at 12 degrees C (Muscatine *et al.*, 1991). During the 2010 cold water event in the Florida Keys, *D. cylindrus* was one of the most affected coral species with 100 percent mortality on surveyed inshore reefs (Kemp *et al.*, 2011).

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *D. cylindrus*'s vulnerabilities to threats as follows: High vulnerability to disease; moderate vulnerability to ocean warming, acidification, trophic effects of fishing, sedimentation, and nutrient enrichment; and low vulnerability to sea level rise, predation, and collection and trade.

The SRR and SIR provided the following information on the susceptibility of *D. cylindrus* to ocean warming. There are conflicting characterizations of bleaching susceptibility of *D. cylindrus* in the literature. The species was bleaching-resistant during the 1983 mass-bleaching event in Florida. Characterizations of the 2005 mass-bleaching event in southern Florida and in the U.S. Virgin Islands noted that no bleached *D. cylindrus* colonies were

observed, but during the same event in Barbados 100 percent of 15 *D. cylindrus* colonies bleached.

Van Woessik *et al.* (2012) developed a coral resiliency index based on biological traits and processes to evaluate extinction risk due to bleaching. Evaluations were performed at the genus level. They rated the resiliency of *D. cylindrus* as 3 out of a range of –6 to 7 observed in other coral genera. Less than or equal to –3 was considered highly vulnerable to extinction, and greater than or equal to 4 was considered highly tolerant. Thus, *D. cylindrus* was rated as moderately tolerant. While this study was included in the SIR, species-specific findings for *Dendrogyra* were not included. The public comments (Comment 47) indicated the results of this study should be considered in the listing status of *D. cylindrus*.

The public comments did not provide new or supplemental information on the susceptibility of *D. cylindrus* to ocean warming. Supplemental information we found confirms the variable susceptibility of *D. cylindrus* to ocean warming and bleaching. *Dendrogyra cylindrus* was among 42 species reported not to have bleached at various locations in the western Atlantic (British Virgin Islands, Jamaica, and Mona Island) during the 1987 bleaching event, while the authors noted these species were reported bleached at other locations or other areas by others (Williams and Bunkley-Williams, 1990). None of the 18 *D. cylindrus* colonies monitored in Roatan, Honduras experienced bleaching or mortality in the 1998 event where bleaching ranged from zero to 89 percent in the 22 species monitored (Riegl *et al.*, 2009). Across 12 locations in Puerto Rico, 100 percent of *D. cylindrus* colonies bleached during the 2005 temperature anomaly (Waddell and Clarke, 2008). However, Bruckner and Hill (2009) report less severe *D. cylindrus* bleaching during the 2005 event in Puerto Rico; approximately 25 percent paled and 10 percent bleached on reefs off Mona and Desecheo Islands, which was relatively low compared to some other species such as *Orbicella faveolata*, which had approximately 60 percent bleached colonies. At Dairy Bull Reef in Jamaica, 50 percent of *D. cylindrus* colonies bleached during the 2005 bleaching event, but no mortality was reported for this species (Quinn and Kojis, 2008). An average of 33 percent of the monitored *D. cylindrus* colonies in the U.S. Virgin Islands bleached in 2005, and 67 percent paled. None of the monitored colonies bleached or paled during the less severe 2010 bleaching event (Smith *et al.*, 2013b).

All sources of information are used to describe *D. cylindrus*'s susceptibility to ocean warming as follows. There are conflicting characterizations of the susceptibility of *D. cylindrus* to bleaching. Some locations experienced high bleaching of up to 100 percent of *D. cylindrus* colonies during the 2005 Caribbean bleaching event while others had a smaller proportion of colonies bleach (10 to 50 percent). Reports of low mortality after less severe bleaching indicate potential resilience, though mortality information is absent from locations that reported high bleaching frequency. Although bleaching of most coral species is spatially and temporally variable, understanding the susceptibility of *D. cylindrus* is further confounded by the species' rarity and, hence, low sample size in any given survey. We conclude that although *D. cylindrus* appears to have resistance to bleaching from warmer temperatures in some portions of its range under some circumstances, it is likely to have some susceptibility to ocean warming, given the high rates of bleaching observed at times. However, the available information does not support a more detailed description of susceptibility.

The SRR and SIR provided the following information on the susceptibility of *D. cylindrus* to acidification. No specific research has addressed the effects of acidification on the genus *Dendrogyra*. However, most corals studied have shown negative relationships between acidification and growth, and acidification is likely to contribute to reef destruction in the future. While ocean acidification has not been demonstrated to have caused appreciable declines in coral populations so far, it is considered a significant threat to corals by 2100.

The public comments did not provide new or supplemental information on the susceptibility of *D. cylindrus* to acidification, and we did not find any new or supplemental information.

All sources of information are used to describe *D. cylindrus*'s susceptibility to acidification as follows. *Dendrogyra cylindrus* likely has some susceptibility to acidification, but the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR provided the following information on the susceptibility of *D. cylindrus* to disease. *Dendrogyra cylindrus* is susceptible to black band disease and white plague, though impacts from white plague are likely more extensive because of rapid progression rates. The large colony size suggests that individual colonies are less likely to suffer complete mortality

from a given disease exposure, but low colony density suggests that even small degrees of mortality increase extinction risk.

The public comments did not provide new or supplemental information on the susceptibility of *D. cylindrus* to disease. Supplemental information we found on the susceptibility of *D. cylindrus* to disease includes the following. In a January 2002 survey at Providencia Island, Colombia, 4.2 percent of *D. cylindrus* colonies (n=185) exhibited white plague type II (Acosta and Acevedo, 2006). The prevalence of diseased *D. cylindrus* colonies was approximately three percent in Mexico from 2002 to 2004 (Ward *et al.*, 2006). Though white diseases were reported to cause colony mortality in some coral species in the U.S. Virgin Islands after the 2005 Caribbean bleaching event, none of the monitored *D. cylindrus* colonies exhibited signs of white disease (Smith *et al.*, 2013b).

All sources of information are used to describe *D. cylindrus*'s susceptibility to disease as follows. Disease appears to be present in about three to four percent of the population in some locations. Because no studies have tracked disease progression in *D. cylindrus*, the effects of disease are uncertain at both the colony and population level. However, the reported low partial mortality and large colony size suggest that individual colonies are less likely to suffer complete colony mortality from a given disease exposure. Therefore, we conclude that *D. cylindrus* has some susceptibility to disease, but the available information does not support a more precise description of susceptibility to this threat.

The SIR and SRR did not provide any species-specific information on the trophic effects of fishing on *D. cylindrus*. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the trophic effects of fishing on *D. cylindrus*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. This effect coupled with the species' low recruitment rate indicates it likely has some susceptibility to the trophic effects of fishing. The available information does not support a more precise description of its susceptibility.

The SRR and SIR provided the following information on the susceptibility of *D. cylindrus* to sedimentation. The rate of sand removal from *D. cylindrus* tissues in laboratory

conditions was intermediate among 19 Caribbean coral species tested.

The public comments did not provide new or supplemental information on the susceptibility of *D. cylindrus* to sedimentation. Supplemental information we found includes the following. *Dendrogyra cylindrus*, along with *Acropora* spp. and *Meandrina meandrites*, was found in fossil assemblages only on the reef tract and not on the lagoonal patch reefs around Grand Cayman, suggesting that this species may be ineffective at sediment rejection like the other two species or may be intolerant of turbidity (Hunter and Jones, 1996).

All sources of information are used to describe *D. cylindrus*'s susceptibility to sedimentation as follows. *Dendrogyra cylindrus* appears to be moderately capable of removing sediment from its tissue. However, *D. cylindrus* may be more sensitive to turbidity due to its high reliance on nutrition from photosynthesis and as evidenced by the geologic record. Therefore, we conclude that *D. cylindrus* has some susceptibility to sedimentation, but the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR provided the following information on the susceptibility of *D. cylindrus* to nutrient enrichment. Along a eutrophication gradient in Barbados, *D. cylindrus* was found at a single site, one of those farthest removed from pollution. The public comments did not provide new or supplemental information on the susceptibility of *D. cylindrus* to nutrient enrichment, and we did not find any new or supplemental information.

All sources of information are used to describe *D. cylindrus*'s susceptibility to nutrient enrichment as follows. *Dendrogyra cylindrus* may be susceptible to nutrient enrichment as evidenced by its absence from eutrophic sites in one location. However, there is uncertainty about whether its absence is a result of eutrophic conditions or a result of its naturally uncommon or rare occurrence. Therefore, we conclude that *D. cylindrus* likely has some susceptibility to nutrient enrichment. However, the available information does not support a more precise description of its susceptibility to this threat.

The SRR and SIR provided the following information on the susceptibility of *D. cylindrus* to predation. The corallivorous fireworm *Hermodice carunculata* has been observed feeding on diseased colonies of *D. cylindrus*, but generally, predation is not observed to cause noticeable

mortality on *D. cylindrus*, despite its rarity.

The public comments did not provide new or supplemental information on *D. cylindrus*'s susceptibility to predation. Supplemental information we found includes the following. The sea urchin, *Diadema antillarum*, has been reported to cause partial mortality at the base of *D. cylindrus* colonies (Acosta and Acevedo, 2006).

All sources of information are used to describe *D. cylindrus*'s susceptibility to predation as follows. The low amounts of observed mortality indicate *D. cylindrus* has low susceptibility to predation.

The SRR and SIR did not provide species-specific information on the effects of sea level rise on *D. cylindrus*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *D. cylindrus*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *D. cylindrus* has some susceptibility to sea level rise, but the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR provided information on *D. cylindrus*'s susceptibility to collection and trade. Overall trade reports indicate very low rates of international trade of *D. cylindrus*. It is possible that historical curio collecting of *D. cylindrus* may have significantly reduced populations off Florida.

The public comments did not provide new or supplemental information of the susceptibility of *D. cylindrus* to collection and trade. Supplemental information we found confirms what was provided by the SRR and SIR. Prior to its ban in the 1980s, collection of *D. cylindrus* for curios was once widespread off the coast of Florida (Florida Fish and Wildlife Conservation Commission, 2013). From 2000 to 2012, international trade of this species was low with gross exports ranging from zero to nine corals per year (average less than two per year; data available at <http://trade.cites.org>).

All sources of information are used to describe *D. cylindrus*'s susceptibility to collection and trade as follows. In the past, collection and trade may have had a large effect on the population in some locations like Florida. However, collection and trade likely does not have a large impact on the population currently. Therefore, we conclude that the susceptibility of *D. cylindrus* to collection and trade is currently low.

## Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *D. cylindrus*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *D. cylindrus* occurs in seven Atlantic ecoregions that encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Caribbean Territories), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *D. cylindrus*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and, second as the percentages of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *D. cylindrus* are reef fishing regulations and area management for protection and conservation. However, half of the reef fishing regulations are limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *D. cylindrus*.

*Dendrogyra cylindrus* is listed as threatened on the State of Florida endangered and threatened species list. The state has an action plan for conservation of the species with several objectives including stabilizing or increasing the existing population, the current area of occupancy, and the

number of sexually mature individuals and evaluating the reproductive potential of the population over the next decade (Florida Fish and Wildlife Conservation Commission, 2013). However, the management plan recognizes that there are threats to *D. cylindrus* that need to be addressed outside the scope of the plan in order to improve the status of this species.

## Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its demographic and spatial characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the extinction risk for *D. cylindrus* include the overall low population density and low population size, gonochoric spawning mode and lack of observed sexual recruitment, and susceptibility to observed disease mortality. The SRR acknowledged that, given the apparent naturally rare status of this species, some undescribed adaptations to low population density may exist in this species, particularly with regard to overcoming fertilization limitation between spawned gametes from gonochoric parent colonies that are at great distance from one another. Nonetheless, the pervasiveness of threats characterizing the Caribbean region was deemed to represent substantial extinction risk given this species' low population size.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *D. cylindrus*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. *Dendrogyra cylindrus* is susceptible to a number of threats, but there is little evidence of population

declines thus far. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *D. cylindrus* is limited to an area with high, localized human impacts and predicted increasing threats. *Dendrogyra cylindrus* inhabits most reef environments in water depths ranging from 1 to 25 m which moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. It is naturally rare. Estimates of absolute abundance are at least tens of thousands of colonies in the Florida Keys, and absolute abundance is higher than estimates from this location due to the occurrence of the species in many other areas throughout its range. It is a gonochoric broadcast spawner with observed low sexual recruitment. Its low abundance, combined with its geographic location, exacerbates vulnerability to extinction because increasingly severe conditions within the species' range are likely to affect a high proportion of its population at any given point in time, and low sexual recruitment is likely to inhibit recovery potential from mortality events, further exacerbating its vulnerability to extinction.

## Listing Determination

In the proposed rule, using the determination tool formula approach, *D. cylindrus* was proposed for listing as endangered because of: High vulnerability to disease (C); moderate vulnerability to ocean warming (E) and acidification (E); rare general range-wide abundance (E); low relative recruitment rate (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *D. cylindrus* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of the buffering capacity of this species' spatial and demographic traits, and the best available information above on *D. cylindrus*'s spatial structure, demography, threat susceptibilities, and management. This combination of factors indicates that *D. cylindrus* is likely to become endangered throughout

its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Dendrogyra cylindrus* is susceptible to ocean warming (ESA Factor E), disease (C), acidification (E), nutrient enrichment (A and E), sedimentation (A and E), and trophic effects of fishing (A). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address global threats (D).

(2) *Dendrogyra cylindrus* is geographically located in the highly disturbed Caribbean where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future;

(3) *Dendrogyra cylindrus* has an uncommon to rare occurrence throughout its range, which heightens the potential effect of localized mortality events and leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections; and

(4) *Dendrogyra cylindrus*'s low sexual recruitment limits its capacity for recovery from threat-induced mortality events throughout its range over the foreseeable future.

The combination of these characteristics and future projections of threats indicates the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *D. cylindrus* spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) There is little evidence of *D. cylindrus* population declines (*i.e.*, the species continues to be naturally rare);

(2) *Dendrogyra cylindrus* shows evidence of resistance to bleaching from warmer temperatures in some portions of its range under some circumstances (*e.g.*, Roatan, Honduras); and

(3) While *D. cylindrus*'s distribution within the Caribbean increases its risk of exposure to threats as described

above, its habitat includes most reef environments in water depths ranging from one to 25 m. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Last, *D. cylindrus* is listed as threatened on the State of Florida endangered and threatened species list, and an action plan for conservation has recently been developed. Implementation of the action plan will no doubt have benefits to the species, but it is too soon to evaluate its effectiveness for conserving the species. Further, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

#### Genus *Dichocoenia*

The SRR and SIR provided the following information on *Dichocoenia*'s morphology and taxonomy. There are potentially two species in the genus *Dichocoenia*: *Dichocoenia stokesi* and *Dichocoenia stellaris*. *Dichocoenia stellaris* has been described as differing from *D. stokesi* by its pancake-like colony morphology and dominance of smaller, circular calices. Some coral taxonomists consider there to be only one species, *D. stokesi*, as specimens have all variations of skeletal shape and valley length. The public comments did not provide any new or supplemental information on *Dichocoenia*'s taxonomy or morphology, and we did not find any new or supplemental information.

Most studies over the last several decades describe *D. stokesi* and do not separately report data for colonies with *D. stellaris* morphology. Because *D. stokesi* was petitioned for listing and *D. stellaris* was not, we considered all information on *D. stokesi* and did not consider information on *D. stellaris*,

despite some uncertainty of whether or not these are the same species. If *D. stokesi* is accepted to include all sizes of calices, it is easy to identify; if not then species delineations are somewhat arbitrary. We did not find any supplemental information on *Dichocoenia*'s taxonomy.

#### *Dichocoenia stokesi*

##### Introduction

*Dichocoenia stokesi* forms mounding-spherical colonies that are usually orange-brown but sometimes green.

##### Spatial Information

The SRR and SIR provided the following information on *D. stokesi*'s distribution, habitat, and depth range. *Dichocoenia stokesi* is located in the western Atlantic, Gulf of Mexico (including the Florida Middle Grounds and Flower Garden Banks), and throughout the Caribbean. It is also reported in Bermuda, though it is rare. *Dichocoenia stokesi* occurs in most reef environments within its range, including mesophotic reefs, back- and fore-reef environments, rocky reefs, lagoons, spur-and-groove formations, channels, and occasionally at the base of reefs. It has been reported in water depths ranging from two to 72 m.

The public comments did not provide any new or supplemental information on *D. stokesi*'s distribution, habitat, or depth range. Supplemental information we found includes the following. Veron (2014) confirmed the occurrence of *D. stokesi* in nine out of 11 ecoregions in the western Atlantic and wider-Caribbean known to contain corals. The two ecoregions in which it is not reported are off the coasts of Brazil, and the southeast U.S. north of south Florida. Kahng *et al.* (2010) report that *D. stokesi* is relatively abundant and dominates the coral community on mesophotic reefs greater than 40 m depth in the northern Gulf of Mexico but not in Belize, Puerto Rico, U.S. Virgin Islands, Jamaica, Curacao, Florida, Bermuda, Bahamas, or Barbados.

All information on *D. stokesi*'s distribution can be summarized as follows. *Dichocoenia stokesi* is distributed throughout most of the greater Caribbean in most reef environments within its range, including mesophotic reefs.

##### Demographic Information

The SRR and SIR provided the following information on *D. stokesi* abundance. *Dichocoenia stokesi* is characterized as usually uncommon. In surveys of southeast Florida and the

Florida Keys between 2005 and 2007, *D. stokesi* comprised between 1.8 and 7.0 percent of all coral colonies observed and was present at a density of approximately 1.7 colonies per 10 m<sup>2</sup>, which was the ninth most abundant out of an observed 43 coral species.

The public comments provided the following supplemental information on *D. stokesi*'s abundance. In stratified random surveys conducted by Miller *et al.* (2013) in the Florida Keys, *D. stokesi* ranked as the 8th most abundant species or higher in 2005, 2009, and 2012. Extrapolated abundance was  $97.8 \pm 13.1$  (SE) million colonies in 2005,  $53.8 \pm 9.7$  (SE) million colonies in 2009, and  $81.6 \pm 10.0$  (SE) million colonies in 2012. Because population estimates were based on random sampling, differences between years are more likely a function of sampling effort rather than an indication of population trends. Most colonies were 30 cm or less in size, and size class distributions remained similar among the three sample periods (2005, 2009, and 2012). Larger colonies typically exhibited more partial mortality, which ranged between 20 and 80 percent for colonies larger than 10 cm.

In the Dry Tortugas, *D. stokesi* was ranked 12th and 14th most common in 2006 and 2008, respectively. Extrapolated colony abundance was  $12.1 \pm 4.1$  (SE) million colonies in 2006 and  $7.1 \pm 1.1$  (SE) million colonies in 2008. All *D. stokesi* colonies observed were 40 cm or less in 2006, and 20 cm or less in 2008. Partial mortality was higher in larger colonies and ranged from approximately 20 to 65 percent in colonies larger than 10 cm (Miller *et al.*, 2013).

Supplemental information we found on *D. stokesi*'s abundance includes the following. In surveys of Utila, Honduras between 1999 and 2000, *D. stokesi* was the eighth most common species and was sighted in 52.6 percent of 784 surveys (Afzal *et al.*, 2001). *Dichocoenia stokesi* has been observed in low abundance at 17 of 33 monitoring sites in the U.S. Virgin Islands and is the 33rd most common species by percent cover (Smith, 2013). Off southeast Florida, *D. stokesi* comprised 6.8 percent of the coral population between 9 and 32 m depth and was ranked the 5th most abundant coral species out of 27 coral species encountered (Goldberg, 1973). In surveys of Conch Reef in the Florida Keys in 1995, juvenile *D. stokesi* comprised between approximately two and six percent of the overall juvenile coral population, and the highest proportion occurred at 14 m and decreased with depth (Edmunds *et al.*, 2004). Off South Caicos Island, *D.*

*stokesi* was most frequently encountered on shallow pavement (9 m) and comprised 15 percent of all coral colonies counted; however on the deeper spur and groove (18 m) and fore-reef (27 m), it comprised 2 and 0.7 percent of colonies counted, respectively (Steiner, 1999). Bak and Meesters (1999) report that about 50 percent of *D. stokesi* colonies surveyed in Florida and Curacao were in the 10 to 20 cm size class.

Between 1996 and 2003, average cover of *D. stokesi* per habitat type ranged from 0.02 to 0.12 percent in the Florida Keys and was highest on patch reefs (Sommerfield *et al.*, 2008). Of three sites surveyed in Bermuda, cover of *D. stokesi* was  $0.02 \pm 0.03$  percent at one site (Dodge *et al.*, 1982). In surveys off Colombia from 1998 to 2004, *D. stokesi* cover ranged from 0.02 to 0.6 percent, but the species was only present in nine out of 32 sites (Rodriguez-Ramirez *et al.*, 2010). In the Bahamas Archipelago, cover of *D. stokesi* was on average 0.01 to 0.02 percent in 2002 to 2004 (Roff *et al.*, 2011). In Dominica, *D. stokesi* was observed in 47 percent of 31 sites surveyed and comprised less than one percent cover (Steiner, 2003). *Dichocoenia stokesi* was present on four out of seven fringing reefs off Barbados and comprised between 0.1 and 0.6 percent cover (Tomascik and Sander, 1987).

On remote reefs off southwest Cuba, *D. stokesi* was observed on 30 reef front sites at densities of  $0.052 \pm 0.096$  (SD) colonies per 10 m transect, but was not observed at any of the 38 surveys of the reef crest (Alcolado *et al.*, 2010). In 1,176 sites surveyed in southeast Florida and the Florida Keys between 2005 and 2010, density of *D. stokesi* ranged from 0.07 to 2.35 colonies per 10 m<sup>2</sup> on reef zones where they were found, and this species was the eighth most abundant species out of 42 coral species encountered (Burman *et al.*, 2012).

The SRR and SIR provided the following information on population trends of *D. stokesi*. A comparison of survey data from 19 sites in Spaanse Water, Curacao in 1961 and 1992 indicated an 80 percent decrease in relative abundance of *D. stokesi* between the two survey periods. In surveys of the Florida Keys between 1995 and 2002 during and after a disease outbreak, the average number of *D. stokesi* colonies per 314-m<sup>2</sup> site decreased from 44.3 to 11.2, a decline of almost 75 percent. The maximum number of *D. stokesi* colonies per site decreased from 95 to 43, and the minimum number of colonies per site decreased from ten to one. There was a

shift in the size class distribution between 1998 and 2002 with a decrease in the frequency of smaller size classes and a shift from dominance by smaller size classes to a more even distribution across small to larger size classes. Two *D. stokesi* recruits were found after the disease but did not survive to the following year. No colonies greater than 25 cm were observed in 1998, four years later (2002) many colonies greater than 25 cm were observed up to 55 cm.

The public comments did not provide new or supplemental information on *D. stokesi*'s population trends, and we did not find any new or supplemental information.

All information on *D. stokesi*'s abundance and population trends can be summarized as follows. *Dichocoenia stokesi* has been characterized as usually uncommon but is usually reported as one of the top 10 most abundant species where estimates are available. Based on population estimates, there are at least tens of millions of *D. stokesi* colonies present in both the Florida Keys and Dry Tortugas. Absolute abundance is higher than the estimate from these two locations given the presence of this species in many other locations throughout its range. The characterization of its occurrence as usually uncommon gives the impression of a lower population abundance than is indicated by population estimates. Density estimates range from 0.05 to 2.35 colonies per 10 m<sup>2</sup>. The sometimes low density and small colony size result in low percent cover estimates, generally between 0.01 and less than 1 percent, and make it difficult to track population trends from percent cover data. Trend data indicate *D. stokesi* has decreased in abundance in at least two locations (*i.e.*, the Florida Keys, and a bay in Curacao). Presence of juveniles in several locations indicates recruitment is occurring. Recovery from severe population declines in the Florida Keys after a disease event was not reported seven years later. Thus, we conclude that population decline has occurred in some locations and that the species' absolute abundance is greater than hundreds of millions of colonies.

#### Other Biological Information

The SRR and SIR provided the following information on *D. stokesi*'s life history. *Dichocoenia stokesi* is a gonochoric broadcast spawner with an overall sex ratio of 2 to 1 (male to female) in southeast Florida where a small portion of hermaphroditic colonies (approximately 18 percent) were observed. Minimum size at reproduction was 160 cm<sup>2</sup>, and two potential spawning events per year were

inferred: one in late August/early September and a second in October. Recruitment levels, inferred from the presence of juveniles, is intermediate compared to other Caribbean coral species. Very low densities of *Dichocoenia* juveniles (approximately one percent of total juvenile colonies) have been observed in the Netherlands Antilles. Mean *D. stokesi* juvenile density among 566 sites surveyed during 1999 to 2009 averaged 0.11 per m<sup>2</sup> but reached as high as one juvenile per m<sup>2</sup> in certain habitats. The annual growth rate of *D. stokesi* has been reported as 2 to 7 mm per year in diameter and 2 to 5.2 mm per year in height.

The public comments did not provide new or supplemental information on the life history of *D. stokesi*. Supplemental information we found on the life history of *D. stokesi* includes the following. Chiappone and Sullivan (1996) reported density of juvenile *D. stokesi* range from 0.02 to 0.26 per m<sup>2</sup> at five out of nine sites surveyed in the Florida Keys between 1993 and 1994. Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Dichocoenia stokesi* was classified as a “stress-tolerant” species, thus likely more tolerant of environmental stress.

The SRR and SIR provided the following other biological information about *D. stokesi*. The mounding morphology and large corallite diameter of *D. stokesi* enhance turbulence near the surface of colonies. This should, in turn, enhance mass transfer, which affects photosynthesis and respiration in *D. stokesi* as well as prey capture and nutrient uptake. Thresholds for uptake of inorganic nitrogen in *D. stokesi* have been reported to be fairly low (150 nM), giving it a potential advantage in nutrient-poor conditions.

The public comments did not provide new or supplemental information on *D. stokesi*'s biology. Supplemental information we found on *D. stokesi*'s biology includes the following. At 76 sites surveyed in the Florida Keys during the 2010 cold-water event, approximately 15 percent of *D. stokesi* paled, and approximately one percent bleached. Mortality was approximately four percent (The Nature Conservancy, 2010).

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *D. stokesi*'s

vulnerabilities to threats as follows: High vulnerability to disease; moderate vulnerability to ocean warming, acidification, trophic effects of fishing, and sedimentation; and low vulnerability to sea level rise, predation, and collection and trade.

The SRR and SIR provided the following information on the susceptibility of *D. stokesi* to ocean warming. Of the 28 coral species that bleached along the Florida reef tract from Martin County through the lower Florida Keys from 2005 to 2007, *D. stokesi* had the lowest bleaching prevalence. During the 2005 Caribbean mass-bleaching event, it ranked 16th of 21 species in bleaching prevalence in Barbados and was observed to be bleaching-tolerant in the U.S. Virgin Islands.

Van Woessik *et al.* (2012) developed a coral resiliency index based on biological traits and processes to evaluate extinction risk due to bleaching. Evaluations were performed at the genus level. They rated the resiliency of *Dichocoenia* as 0 out of a range of -6 to 7 observed in other coral genera. Less than or equal to -3 was considered highly vulnerable to extinction, and greater than or equal to 4 was considered highly tolerant. Thus, *Dichocoenia* was rated in the middle.

The public comments did not provide new or supplemental information on the susceptibility of *D. stokesi* to ocean warming. Supplemental information we found on the susceptibility of *D. stokesi* to ocean warming includes the following. During the 1998 bleaching event, an average of 20 percent of *D. stokesi* colonies were greater than 50 percent bleached in the lower Florida Keys and Dry Tortugas; however, this was the lowest of 14 species that bleached (Waddell, 2005). Of the 22 species monitored off Roatan, Honduras, *D. stokesi* was one of eight species that did not bleach during the 1998 bleaching event (Riegl *et al.*, 2009).

During the 2005 temperature anomaly, *D. stokesi* colonies were fully bleached around La Parguera, Puerto Rico but were less frequently bleached at other locations around Puerto Rico (Waddell and Clarke, 2008). Off of Mona and Desecheo Islands, Puerto Rico, about 25 percent of *D. stokesi* paled and about 10 percent bleached; in the 16 coral species surveyed, bleaching ranged from less than five percent to approximately 60 percent of colonies (Bruckner and Hill, 2009). During the 2005 bleaching event, approximately 30 percent of *D. stokesi* colonies on six reefs bleached in Barbados, and *D. stokesi* around Grand Cayman experienced total bleaching (Wilkinson

and Souter, 2008). None of the monitored *D. stokesi* colonies in the U.S. Virgin Islands bleached, and 67 percent paled during the 2005 bleaching event (Smith *et al.*, 2013b). In the Florida Keys, *D. stokesi* ranked 19th out of 25 species in amount of mortality during the 2005 bleaching event (Lirman *et al.*, 2011).

All sources of information are used to describe *D. stokesi*'s susceptibility to ocean warming as follows. Reported bleaching of *D. stokesi* ranges from zero to about 60 percent. While reported bleaching of *D. stokesi* is temporally and spatially variable, compared to other Caribbean coral species, *D. stokesi* appears to be among the less susceptible to temperature-induced bleaching. Additionally, a report from the Florida Keys indicates that bleaching-induced mortality of *D. stokesi* was among the lowest compared to other Caribbean coral species. Thus, we conclude that *D. stokesi* has some susceptibility to ocean warming. However, the available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on the susceptibility of *D. stokesi* to acidification. No specific research has addressed the effects of acidification on the genus *Dichocoenia*. However, most corals studied have shown negative relationships between acidification and growth, and acidification is likely to contribute to reef destruction in the future. While ocean acidification has not been demonstrated to have caused appreciable declines in coral populations so far, it is considered a significant threat to corals by 2100.

The public comments did not provide new or supplemental information on the susceptibility of *D. stokesi* to acidification, and we did not find any new or supplemental information.

All sources of information are used to describe *D. stokesi*'s susceptibility to acidification as follows. There is uncertainty about how *D. stokesi* will respond to ocean acidification, but based on the negative effects of acidification on growth of most corals, *D. stokesi* likely has some susceptibility to acidification. The available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on *D. stokesi*'s susceptibility to disease. Black band disease, dark spot syndrome, and white plague have been reported to affect *D. stokesi*. In an outbreak of white plague in St. Lucia in 1997, six surveyed colonies of *D. stokesi* were infected, and average tissue mortality was about 65 percent. In surveys in Dominica

between 2000 and 2002, *D. stokesi* was one of four coral species most commonly affected by disease, and white plague predominantly affected larger-sized colonies. Of 17 species affected by white plague in the Florida Keys, *D. stokesi* was the most susceptible.

The public comments did not provide new or supplemental information on the susceptibility of *D. stokesi* to disease. Supplemental information we found on the susceptibility of *D. stokesi* to disease includes the following. In 1991, an outbreak of white plague was observed on Mona Island, Puerto Rico that affected 14 species, with the highest prevalence among small, massive corals including *D. stokesi*, many of which died within one to two weeks (Waddell, 2005). In Mexico, disease was prevalent on approximately one percent of *D. stokesi* colonies surveyed in 2004 (Ward *et al.*, 2006).

During an outbreak of white plague type II in the Florida Keys in 1995, mortality of *D. stokesi* averaged 26 percent and ranged from 0 to 38 percent (Richardson *et al.*, 1998). The disease routinely caused whole colony mortality within two to three days due to its infection of small coral colonies (usually less than 10 cm in diameter) and aggressive progression rate (up to 2 cm per day; Richardson, 1998). Between 1996 and 1998, out of 160 monitoring stations at 40 sites in the Florida Keys, the number of stations with *D. stokesi* colonies affected by disease increased through time with two stations affected in 1996, 22 in 1997, and 45 in 1998 (Porter *et al.*, 2001). However, no white plague was observed in *D. stokesi* in 2002 at the sites with the reported outbreak in 1995 (Richardson and Voss, 2005).

Disease surveys at St. Croix, U.S. Virgin Islands during the summer of 2001 revealed that *D. stokesi* had the highest prevalence of white plague type II out of seven species infected and the highest disease-related mortality (Kaczmarek *et al.*, 2005). The prevalence of white plague type II on *D. stokesi* was 41 percent at one location and 60 percent at a second site. Of 107 *D. stokesi* colonies, 38 were infected, and 26 percent of the infected colonies, or 9.4 percent of the sample population, died within two months (Kaczmarek *et al.*, 2005). After the 2005 bleaching event, 100 percent of monitored *D. stokesi* colonies in the U.S. Virgin Islands were infected with disease in 2006, but none of the colonies experienced total colony mortality (Smith *et al.*, 2013b).

All sources of information are used to describe *D. stokesi*'s susceptibility to

disease as follows. Although *D. stokesi* is susceptible to several diseases, the most severe impacts have been the result of white plague. Low prevalence of diseased *D. stokesi* colonies have been reported from some locations, but outbreaks of white plague have caused rapid and substantial mortality in some other sites. Outbreaks in Puerto Rico and St. Lucia, while affecting *D. stokesi*, do not appear to have caused as severe mortality as in the Florida Keys and U.S. Virgin Islands. Thus, we conclude that *D. stokesi* has high susceptibility to disease.

The SIR and SRR did not provide any species-specific information on the trophic effects of fishing on *D. stokesi*. The public comments did not provide any new or supplemental information on the trophic effects of fishing on *D. stokesi*, and we did not find any new or supplemental information. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. Based on *D. stokesi*'s inferred recruitment rates, we conclude that it likely has low susceptibility to trophic effects of fishing.

The SRR and SIR provided the following information on susceptibility of *D. stokesi* to sedimentation. A laboratory study examining oil/sediment rejection indicated that out of 19 Caribbean coral species examined, *D. stokesi* was intermediate in the rate of sediment removal from its tissues. In laboratory experiments, *D. stokesi* exhibited significant increases in respiration after 3 days of exposure to turbidity levels of 28 to 30 NTU, which are within allowable levels as regulated by the State of Florida for coastal construction projects. While light levels and photosynthesis were not affected, after six days of exposure to 14 to 16 NTU of turbidity, gross photosynthesis to respiration ratios were less than one in this species, and excessive mucus production was observed.

The public comments did not provide new or supplemental information on the susceptibility of *D. stokesi* to sedimentation. Supplemental information we found on the susceptibility of *D. stokesi* to sedimentation includes the following. The large calices, number of septa, and calical relief of *D. stokesi* give this species the capability to remove both fine sediment and larger grain sizes through polyp distension (Hubbard and Pocock, 1972).

All sources of information are used to describe *D. stokesi*'s susceptibility to sedimentation as follows. *Dichocoenia*

*stokesi* is more tolerant of sedimentation than other coral species as it has the ability to remove both larger grain size and finer sediment. However, prolonged exposure (several days) to turbidity has been shown to cause physiological stress. We conclude that *D. stokesi* has some susceptibility to sedimentation. However, the available information does not support a more precise description of susceptibility.

The SRR and SIR did not provide any species or genus information on the susceptibility of *D. stokesi* to nutrients but provided the following. Land-based sources of pollution (including nutrients) often act in concert rather than individually and are influenced by other biological (*e.g.*, herbivory) and hydrological factors. Collectively, land-based sources of pollution are unlikely to produce extinction at a global scale; however, they may pose significant threats at local scales and reduce the resilience of corals to bleaching.

The public comments did not provide new or supplemental information on the susceptibility of *D. stokesi* to nutrients, and we did not find any new or supplemental information. Based on our knowledge that nutrients in general have a negative effect on corals, we conclude that *D. stokesi* has some level of susceptibility to nutrients, but the available information does not support a more precise description of susceptibility.

The SRR and SIR provided the following information on the susceptibility of *D. stokesi* to predation. *Dichocoenia stokesi* is minimally affected by predation. Sponges such as *Chondrilla nucula* and *Ectoplaysia ferox* can overgrow and cause tissue loss in *D. stokesi*, especially if unchecked by spongivores. *Dichocoenia stokesi* had the highest density of boring bivalves (average 7.5 bivalves per colony) of the three coral species examined.

The public comments provided supplemental information on *D. stokesi*'s susceptibility to predation. Predation by *Coralliophila* snails was recorded on 1.8 percent of the 502 *D. stokesi* colonies assessed for condition in 2012 surveys in the Florida Keys (Miller *et al.*, 2013). We did not find any new or supplemental information on the susceptibility of *D. stokesi* to predation.

All sources of information confirm that predation does not appear to significantly affect *D. stokesi*. Thus, we conclude that *D. stokesi* has low susceptibility to predation.

The SRR and SIR provided the following information on the susceptibility of *D. stokesi* to collection and trade. Collection and trade are not considered a threat to *D. stokesi*. The

public comments did not provide new or supplemental information. Supplemental information we found on collection and trade includes the following. Collection and trade of *D. stokesi* appear to be low and primarily for scientific purposes. Gross exports between 2000 and 2012 averaged 35 corals per year (data available at <http://trade.cites.org>). Thus, we conclude that *D. stokesi* has low susceptibility to collection and trade.

The SRR and SIR did not provide species-specific information on the effects of sea level rise on *D. stokesi*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *D. stokesi*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *D. stokesi* has some susceptibility to sea level rise, but the available information does not provide a more precise description of susceptibility.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanism or conservation efforts for *D. stokesi*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *Dichocoenia stokesi* occurs in nine Atlantic ecoregions that encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Overseas Territories), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *D. stokesi*, described first as a percentage of the above countries and kingdoms that utilize them to any degree, and second as the percentages of those countries and kingdoms whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in

scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *D. stokesi* are reef-fish fishing regulations and area management for protection and conservation. However, half of the reef-fish fishing regulations are limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *D. stokesi*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the potential extinction risk for *D. stokesi* include documented population-level impacts from disease. Factors that reduce potential extinction risk are relatively high abundance and persistence across many habitat types, including nearshore and mesophotic reefs. Residency in a wide range of habitat types suggests the species has a wide tolerance to environmental conditions and, therefore, better capacity to deal with changing environmental regimes.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *D. stokesi*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Although it is

geographically located in the heavily disturbed Caribbean, *D. stokesi* occurs in a wide range of habitats, including mesophotic reefs, back- and fore-reef environments, rocky reefs, lagoons, spur-and-groove formations, channels, and occasionally at the base of reefs. This distribution in a wide range of environments suggests the species will be better able to withstand changing environmental conditions and moderates vulnerability to extinction over the foreseeable future because the numerous types of reef environments in which the species occurs are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. It has been reported in water depths ranging from 2 to 72 m. Deeper areas of *D. stokesi*'s range will usually have lower temperatures than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. The species is highly susceptible to disease, and outbreaks have resulted in high colony mortality in some locations in its range. However, *D. stokesi*'s abundance has been estimated as at least tens of millions of colonies in both the Florida Keys and Dry Tortugas and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. Additionally, sexual recruitment, as evidenced by presence of juvenile colonies, is comparatively higher than many other Caribbean coral species, enhancing recovery potential from mortality events, thus moderating vulnerability to extinction. The combination of wide habitat occupancy, abundance, life history characteristics, and depth distribution, combined with spatial variability in ocean warming and acidification across the species' range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *D. stokesi* was proposed for listing as threatened because of: High vulnerability to disease (C); moderate vulnerability to ocean warming (E) and acidification (E); moderate overall distribution (based on narrow geographic distribution and wide depth distribution (E)); restriction to the

Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *D. stokesi* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *D. stokesi*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time because:

(1) *Dichocoenia stokesi*'s distribution in depths of two to 72 m in heterogeneous habitats, including mesophotic reefs, back- and fore-reef environments, rocky reefs, lagoons, spur-and-groove formations, channels, and occasionally at the base of reefs, throughout the Caribbean basin reduces exposure to any given threat event or adverse condition that does not occur uniformly throughout the species' range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Dichocoenia stokesi* is usually reported in the top ten most abundant coral species in the Caribbean, and its total absolute abundance is at least tens of millions of colonies based on estimates from two locations. Absolute abundance is higher than estimates from these locations since it occurs in many other locations throughout its range. This provides buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response;

(3) *Dichocoenia stokesi* occurs in most reef habitats, including mesophotic reefs, back- and fore-reef environments, rocky reefs, lagoons, spur-and-groove formations, channels, and occasionally at the base of reefs, indicating wide tolerance of environmental conditions and better capacity to deal with changing environmental regimes; and

(4) Presence of juvenile *D. stokesi* colonies indicates that recruitment is likely occurring, enhancing recovery potential from mortality events.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. This species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, *D. stokesi* is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *D. stokesi* is not warranted for listing at this time under any of the listing factors, and we withdraw our proposal to list the species as threatened.

#### Genus *Orbicella* (formerly *Montastraea*)

##### Introduction

The SRR and SIR provided the following information on the taxonomy and morphology of the genus *Montastraea*. The genus *Montastraea* contained four Caribbean species: *M. cavernosa*, *M. annularis*, *M. faveolata*, and *M. franksi*. Prior to the 1990s, *M. annularis*, *M. faveolata*, and *M. franksi* were considered one species, *M. annularis*. However, *M. annularis* was broken into the three sibling species based on behavioral, biochemical, and morphological criteria. These three species are often grouped into the *M. annularis* species complex. Subsequent reproductive and genetic studies have generally supported the partitioning of the complex into three species. *Montastraea faveolata* is the most genetically distinct while *M. annularis* and *M. franksi* are less so.

The public comments provided the following new information on *Montastraea*'s taxonomy. In 2012, the genus *Montastraea* was split, and *M. annularis*, *M. faveolata*, and *M. franksi* were assigned to the genus *Orbicella* (Budd *et al.*, 2012). From this point forward, we will refer to the genus and

species by their current taxonomic classification in the genus *Orbicella*. We did not find any new or supplemental information on *Orbicella*'s taxonomy or morphology.

Some studies report on the species complex rather than individual species since visual distinction can be difficult from video or photographic surveys or in small colonies where morphology is more difficult to discern. This section will report information on the species complex and on *O. annularis* from studies pre-dating 1994 when the species was split into three nominal species.

##### Spatial Information

The SRR and SIR provide the following information on *Orbicella*'s distribution, habitat, and depth range. The species complex has been found at depths to 90 m. It is dominant on mesophotic reefs in Puerto Rico and the U.S. Virgin Islands at depths of 30 to 45 m, and it is found at depths up to 70 to 90 m in these locations.

The public comments did not provide new or supplemental information on *Orbicella*'s distribution, habitat, or depth range. Supplemental information we found on *Orbicella*'s depth range includes the following. All three species occupy a large depth range. Although there is depth overlap in species occurrence, there is larger variance and overlap in species abundances in shallow versus deep water (Pandolfi and Budd, 2008). *Orbicella faveolata* tends to have the shallowest depth distribution, and *O. franksi* tends to have the deepest (Pandolfi and Budd, 2008; Weil and Knowlton, 1994). At three study sites in Belize, *O. faveolata* was the most abundant member of the species complex between 2 and 5 m depth; *O. annularis* was the most abundant at depths of 10 to 15 m, and *O. franksi* was the most abundant at depths of 20 to 30 m (Pandolfi and Budd, 2008). *Orbicella annularis* species complex can be relatively abundant at mesophotic depths in the Bahamas, Belize, Jamaica, Puerto Rico, U.S. Virgin Islands, and Curacao (Kahng *et al.*, 2010).

##### Demographic Information

The SRR and SIR provided the following information on abundance and population trends of the *Orbicella annularis* species complex. The species complex has historically been a dominant component on Caribbean coral reefs, characterizing the so-called "buttress zone" and "annularis zone" in the classical descriptions of Caribbean reefs. The species complex is the major reef-builder in the greater Caribbean,

since the die-off of *Acropora* spp., due to their large size and high abundance.

Numerous examples of population decline of the *Orbicella annularis* species complex were described, and the results are summarized as follows. Decline in the Florida Keys between the late 1970s and 2003 was approximately 80 to 95 percent, with further losses during the 2012 cold weather event. Decadal-scale declines across the remote islands of Navassa, Mona, and Desecheo in the central Caribbean impacted 85 percent of colonies found there. In the U.S. Caribbean (U.S. Virgin Islands and Puerto Rico), an 80 to 90 percent decline has been reported over the past two decades. Percent cover was reportedly stable in Curacao in the mid-1970s, an 85 percent increase in partial mortality occurred between 1998 and 2005. Between 1975 and 1998 at Glovers Reef in Belize, a 38 to 75 percent decline in relative cover occurred with a further 40 percent decline since. Colonies in Colombia were stable between 1998 and 2003 although demographic changes imply some degree of decline. Surveys of population structure across five countries found a significant increase in small ramets (tissue isolates that are genetically identical but physiologically separate from the parent colony) less than 500 cm<sup>2</sup> (211 percent for *O. annularis*, 168 percent for *O. faveolata*, 137 percent for *O. franksi*), while the proportion of large (1,500- 30,000 cm<sup>2</sup>), completely live colonies declined by 51 to 57 percent.

The public comments did not provide new or supplemental information on *Orbicella*'s abundance and population trends. Supplemental information we found on *Orbicella*'s abundance and population trends is provided as follows. In a survey of 185 sites in five countries (Bahamas, Bonaire, Cayman Islands, Puerto Rico, and St. Kitts and Nevis) between 2010 and 2011, *Orbicella annularis* species complex exhibited mean tissue mortality of 29 to 66 percent, which was higher than other species exhibiting mean 8 to 17 percent tissue mortality. Total mortality of *O. annularis* species complex were observed (five to seven percent of the total); however mortality of large colonies mostly resulted in multiple smaller ramets. Mortality was attributed primarily to outbreaks of white plague and yellow band disease, which emerged as corals began recovering from mass bleaching events. This was followed by increased predation and removal of live tissue by damselfish to cultivate algal lawns (Bruckner, 2012a).

In 1998 *O. annularis* species complex covered more of the benthos than any other coral taxon at nine monitored sites

off Mona and Desecheo Islands, Puerto Rico: 47 percent on reefs off Desecheo Island and 32 percent off Mona Island. In 2008 live cover of *O. annularis* species complex ranged from 0 to 14 percent with 95 percent decline off Desecheo Island and 78 percent decline off Mona Island. This was accompanied with large changes in the size frequency distribution and extent of partial mortality, with size structure remaining constant. The amount of living tissue declined by 55 percent due to partial mortality affecting medium and large colonies, with an increase in the number of colonies with small (less than 10 cm diameter) tissue remnants. Sponges and macroalgae colonized newly exposed area, and sponges appeared to be preventing re-sheeting of tissue remnants. No *Orbicella* spp. recruits were observed during the ten year study (Bruckner and Hill, 2009).

Surveys at three reefs in western Curacao in 1998 found 46 percent of all corals were *O. annularis* species complex. In 2005, *O. annularis* species complex remained the dominant coral species but declined in abundance to 38 percent of the overall coral population (decreases in abundance occurred in *O. faveolata* and *O. annularis*, but not *O. franksi*). In 1998 mean diameter of *O. annularis* species complex colonies were 62 cm and less than 10 percent of all *O. annularis* species complex colonies were less than 30 cm in diameter. Partial mortality of *O. annularis* species complex increased 85 percent between 1997 and 2005 with losses of *O. annularis* and *O. faveolata* (partial mortality 42 to 48 percent and total mortality 6 percent for the two species combined) larger than *O. franksi*. The most significant losses were due to yellow band disease and white plague. No recruits of *O. annularis* species complex were observed between 1997 and 2005 in transects or on skeletons of tagged colonies exposed through mortality from disease (Bruckner and Bruckner, 2006a).

McClanahan and Muthiga (1998) surveyed 20 patch reefs in Glovers Reef atoll off Belize between 1996 and 1997 and compared their results to surveys of 16 patch reefs in the same general area conducted between 1970 and 1971. They found that *O. annularis* species complex experienced an overall 62 percent decrease in cover. Average cover of *O. annularis* species complex was seven percent in 1996 and 1997.

The *O. annularis* species complex often makes up the largest proportion of coral cover on Caribbean reefs. In surveys conducted on four reefs in Biscayne National Park, Florida in 1981, cover of *O. annularis* species complex

ranged between approximately 25 and 50 percent on three of the reefs, and no *O. annularis* species complex colonies were observed in transects on the fourth reef (Burns, 1985). In stratified random surveys in 2007–2008, *O. annularis* species complex was the dominant coral by percent cover in the Red Hind Marine Conservation District off St. Thomas, U.S. Virgin Islands, at depths of 34 to 47 m. *Orbicella annularis* species complex averaged 15 percent cover (range zero to 48 percent) and made up 92 percent of the 25 percent average coral cover (Nemeth *et al.*, 2008).

In a survey of 185 sites in five countries (Bahamas, Bonaire, Cayman Islands, Puerto Rico, and St. Kitts and Nevis) in 2010 to 2011, density of *O. annularis* species complex ranged from 0.3 to 2.7 colonies per m<sup>2</sup> and comprised between 9 and 30 percent of all corals greater than 4 cm diameter. The mean diameter ranged from 44 to 89 cm, and the size structure (planar surface area) had a bell shaped distribution, with only a few colonies less than 500 cm<sup>2</sup> or greater than 10,000 cm<sup>2</sup> (Bruckner, 2012a).

In surveys of juvenile corals (less than 4 cm diameter) on nine reefs in the Florida Keys between 1993 and 1994, density of *O. annularis* species complex ranged between 0.02 and 0.04 juvenile corals per m<sup>2</sup> on six of the nine reefs. Density of *O. annularis* species complex juveniles was correlated with non-juvenile *O. annularis* species complex density and with depth. The majority of non-juveniles were smaller than the reproductive size of 100 cm<sup>2</sup> (Chiappone and Sullivan, 1996).

Surveys in Bonaire in 2008 showed that the *O. annularis* species complex dominated coral cover in depths less than 20 m and cover was similar to that reported in 1982. However, all sites surveyed in 2008 showed signs of disease and partial mortality in a large number of the massive colonies, and many were reduced to a patchwork of live tissue and dead areas colonized by algae (Stokes *et al.*, 2010).

At 25 sites surveyed in Bonaire in 2011, *O. annularis* species complex was the dominant coral taxa occupying approximately 20 to 25 percent of the benthos and making up 46 percent of the total live coral cover. It was dominant in terms of abundance, making up approximately 27 percent of all corals. *Orbicella annularis* was significantly more abundant than *O. franksi* and *O. faveolata* on the northern reefs but not on southern reefs. Most colonies were between 30 and 80 cm diameter with size structure of *O. annularis* species complex in a bell

shaped distribution around this range; there were few colonies less than 20 cm and few very large colonies greater than 200 cm, with a small peak at the 150 to 199 cm range. There was a notable absence of colonies less than 10 cm diameter (as measured by the skeleton, not live tissue) and an absence of recruits. A total of 73 out of 1602 colonies (4.5 percent) had completely died. Surviving colonies (n=1529) had a mean of 28 percent partial mortality. On average, each colony was divided into 6.6 tissue remnants. Several sites contained a high abundance of large, unblemished *O. annularis* species complex colonies (Bruckner, 2012c).

Between 1999 and 2009, overall cover of *O. annularis* species complex in the Florida Keys declined, but differed by habitat type (Ruzicka *et al.*, 2013). Percent cover declined on the deep and shallow fore-reefs but remained stable on patch reefs (Ruzicka *et al.*, 2013). The 2010 cold-water event reduced cover of *O. annularis* species complex from 4.4 percent to 0.6 percent on four patch reefs in the upper and middle Florida Keys. Greater than 50 percent of *O. annularis* species complex colonies across all size classes suffered lethal or severe mortality, and 93 percent of all *O. annularis* species complex colonies surveyed suffered complete or partial mortality. The species complex suffered the highest mortality of all coral species affected (Colella *et al.*, 2012). A comparison of 1995 and 2005 surveys of *O. annularis* species complex at 13 patch reefs in the Florida Keys reported ten sites had between 5 and 40 percent more dead areas (Gischler, 2007).

Density of juvenile *O. annularis* species complex increased from 0.07 juveniles per m<sup>2</sup> prior to 2008, to 0.15 juveniles per m<sup>2</sup> and continued at 0.12 juveniles per m<sup>2</sup> in 2009 at 4 km area on the south side of St. John, U.S. Virgin Islands that has been monitored for 16 years. These densities were driven by seven to nine colonies per year, and the increased density did not extend outside the initial survey area when expanded to other areas around St. John. While not possible to distinguish the species in the field, the authors conclude juveniles were most likely *O. annularis* due to the abundance of *O. annularis* on adjacent reefs and the rarity of the presence of the other two species in water less than 9 m (Edmunds *et al.*, 2011).

At Yawzi Point, St. John, U.S. Virgin Islands, the percentage of total coral cover declined by more than 50 percent between 1987 to 1998, from 45 percent to 20 percent. In 1988, 94 percent of the coral cover at Yawzi was *O. annularis* species complex mostly *O. annularis* (97

percent), with a few colonies of *O. faveolata* (6 percent). Despite a reduction in total cover, *O. annularis* species complex remained spatially dominant in 1998 at 96 percent of the coral cover (Edmunds, 2002). Coral cover at this site again declined an additional 65 percent between 1999 and 2011 to seven percent cover, with *O. annularis* species complex remaining dominant at 77 percent of the coral cover (Edmunds, 2013).

At Tektite Reef, St. John, U.S. Virgin Islands, total coral cover increased from 32 percent in 1987 to 43 percent in 1998 but then decreased to 29 percent in 2011 (Edmunds, 2002; Edmunds, 2013). In 1988, 79 percent of the species complex was *O. annularis*, with lesser amounts of *O. faveolata* (one percent) and *O. franksi* (21 percent) (Edmunds, 2002). Greater than 72 percent of coral was *O. annularis* species complex in all survey years (Edmunds, 2013).

Surveys of the Flower Garden Banks between 1974 and 1980 found cover of *O. annularis* species complex between approximately 23 and 40 percent in areas less than 36 m depth (Bright *et al.*, 1984). *Orbicella annularis* species complex was the dominant coral between 2002 and 2003 at 32 percent cover (Aronson *et al.*, 2005). In random surveys between 2002 and 2006, *O. annularis* species complex (predominantly *O. franksi*) was the dominant coral in the Flower Garden Banks comprising between 27 and 40 percent benthic cover (Hickerson *et al.*, 2008). In permanent photo quadrats (8 m<sup>2</sup> total), cover of *O. annularis* species complex (as measured by planar surface area of individual colonies) fluctuated between approximately 20 and 45 percent cover in the East Flower Gardens between 1992 and 2006 with periods of sharp increase and decrease in cover (Hickerson *et al.*, 2008). Cover in west Flower Gardens was between 22 and 40 percent over the same time period and had less annual variability and a generally increasing or stable trend through time (Hickerson *et al.*, 2008).

Surveys of five sites in the Mexican Yucatan in 1985 and 2005 revealed a decrease in relative cover of *O. annularis* species complex. At four out of the five sites, cover of *O. annularis* species complex decreased from between approximately 50 and 60 percent in 1985 to between approximately 10 and 25 percent in 2005. The fifth site had a less dramatic decrease in relative cover from approximately 35 percent to 30 percent cover during this 20-year interval. Disease appeared to be the main cause

of decline, but hurricanes may have also played a role (Harvell *et al.*, 2007).

Size transition matrices were derived from *Orbicella* growth, mortality, and recruitment rates between 1998 and 2003 from four sites in the lower Florida Keys. Forecasting 15 years into the future predicted a steady decline in all size classes except the smallest (less than 5 cm) due to insufficient recruitment to offset mortality and low growth rates of the smaller size classes. Mortality rates were assumed at approximately 40 percent for the smallest size class declining to about 5 percent for the largest (Smith and Aronson, 2006).

All information on *Orbicella*'s abundance and population trends can be summarized as follows. The *O. annularis* species complex historically dominated fore-reef sites throughout the Caribbean both in abundance and cover and formed dense assemblages of large, hundreds-of-years old colonies and few small colonies (Bruckner, 2012a). However, recent declines in *O. annularis* species complex cover have been reported. Major declines range from approximately 50 to 95 percent in locations including Puerto Rico, Belize, the Florida Keys, Mexico, and the U.S. Virgin Islands, and lower levels of decline (5 to 33 percent) have been reported at individual sites within some of these same locations. There have also been reports of more stable percent cover trends (*e.g.*, Bonaire) and periods of increase (*e.g.*, Flower Garden Banks). Observed declines in total coral cover in the Caribbean, since the major decline of *Acropora* spp. in the 1980s, have often been a result of the decline of the *O. annularis* species complex since the taxa can make up a large proportion of the total coral cover. Despite decreases, the *O. annularis* species complex continues to be reported as the dominant coral taxa, albeit at times its relative dominance has decreased to a lower percentage of the total coral cover (*e.g.*, Curacao, U.S. Virgin Islands).

#### Other Biological Information

The SRR and SIR provided the following information on *Orbicella* life history. *Orbicella* spp. have growth rates of approximately 1 cm per year, ranging from 0.06 to 1.2 cm per year. They grow more slowly in deeper water and in less clear water. Large colonies have lower total mortality rates than juvenile and small colonies.

All three species of the *O. annularis* complex are hermaphroditic broadcast spawners, with spawning concentrated on six to eight nights following the full moon in late August, September, or early October. *Orbicella faveolata* is

largely reproductively incompatible with *O. franksi* and *O. annularis*, and it spawns about one to two hours earlier. Fertilization success measured in the field was generally below 15 percent for all three species being closely linked to the number of colonies concurrently spawning. In Puerto Rico, minimum size at reproduction for the *O. annularis* species complex was 83 cm<sup>2</sup>.

Successful recruitment by the *O. annularis* species complex species has seemingly always been rare. Only a single recruit of *Orbicella* was observed over 18 years of intensive observation of 12 m<sup>2</sup> of reef in Discovery Bay, Jamaica. Many other studies throughout the Caribbean also report negligible to absent recruitment of the species complex.

The public comments did not provide new or supplemental information on the life history of *Orbicella*. Supplemental information we found on the life history of *Orbicella* includes the following. *Orbicella franksi* spawns an average of 110 minutes before *O. annularis*, and 120 minutes before *O. faveolata* (Fogarty *et al.*, 2012a). Gametes can disperse over 500 m in 100 minutes, and *O. franksi* sperm viability decreases after two hours (Levitan *et al.*, 2004). *Orbicella franksi* and *O. annularis* gametes are compatible, though other mechanisms associated with the temporal isolation of spawning, including gamete aging, dilution, and dispersal, make hybridization less likely (Knowlton *et al.*, 1997; Levitan *et al.*, 2004). All three species are largely self-incompatible (Knowlton *et al.*, 1997; Szmant *et al.*, 1997). Size at sexual maturity is generally about 200 cm<sup>2</sup> (Szmant-Froelich, 1985). Colonies that were fragmented experimentally to sizes smaller than 100 cm<sup>2</sup> were generally found to have lower fecundity indicating that frequent fragmentation and partial mortality can affect reproductive capacity (Szmant-Froelich 1985).

Smith and Aronson (2006) reported 18 *Orbicella* recruits between 1998 and 2003 in 384 permanent monitoring quadrats (237 m<sup>2</sup>) in the lower Florida Keys. The ability of the species complex to dominate with such low recruitment rates has been described as a storage effect whereby large, old colonies are able to persist and maintain the population until favorable conditions for recruitment occur (Edmunds and Elahi, 2007). However, potential problems may exist for species employing storage effects if favorable conditions for recruitment occur so infrequently that they fall outside the life span of the cohort (Foster *et al.*, 2013).

All sources of information are used to summarize *Orbicella*'s life history as follows. *Orbicella* species have slow growth rates, late reproductive maturity, and low recruitment rates. Colonies can grow very large and live for centuries. Large colonies have lower total mortality than small colonies, and partial mortality of large colonies can result in the production of ramets. The historical absence of small colonies and few observed recruits, even though large numbers of gametes are produced on an annual basis, suggests that recruitment events are rare and were less important for the survival of the *O. annularis* species complex in the past (Bruckner, 2012a). Large colonies in the species complex maintain the population until conditions favorable for recruitment occur; however, poor conditions can influence recruitment periodicity. While the life history strategy of the *O. annularis* species complex has allowed the taxa to remain abundant, we conclude that the buffering capacity of this life history strategy has been reduced by recent population declines and partial mortality, particularly in large colonies.

The SRR, SIR, and public comments did not provide other biological information on the *Orbicella annularis* species complex. Supplemental biological information we found on *Orbicella* is provided as follows. The *Orbicella annularis* species complex is sensitive to cold water. In laboratory experiments, *O. annularis* species complex released zooxanthellae when shocked with cold water between 12 and 18 degrees C, and the response decreased with increasing temperature (Muscatine *et al.*, 1991).

#### Susceptibility to Threats

The SRR and SIR provided the following information on *Orbicella*'s susceptibility to ocean warming. The *Orbicella annularis* species complex is moderately to highly susceptible to bleaching. The composition of zooxanthellae in at least some areas changes in response to bleaching. Bleaching has been shown to prevent reproduction in the following season after recovering normal pigmentation. Particularly well documented mortality following severe mass bleaching in 2005 highlights the immense impact thermal stress events and their aftermath can have on the *Orbicella annularis* species complex. A significant correlation was found between bleaching in 2005 and the prevalence of yellow band disease and white plague affecting the *Orbicella* species complex. Additionally, in laboratory experiments, mortality due to

yellow band disease increased with increasing temperatures.

The public comments did not provide new or supplemental information on the susceptibility of *Orbicella* to ocean warming. Supplemental information we found on *Orbicella*'s susceptibility to ocean warming confirms and expands the information in the SRR and SIR. The *O. annularis* species complex often has one of the highest bleaching levels among reported species. Extended recovery times have been reported, and disease outbreaks have often followed bleaching events. On Carysfort Reef in the Florida Keys, greater than 90 percent of *O. annularis* species complex colonies were bleached in March 1988 after the 1987 Caribbean bleaching event; however, no colony mortality was observed between 1986 and 1988 (Fitt *et al.*, 1993). Colonies of the *O. annularis* species complex in the Florida Keys that remained bleached seven months following the 1987 bleaching event experienced reproductive failure during the reproductive season following the bleaching event. Colonies that recovered after bleaching events were able to follow a normal reproductive cycle, but bleached colonies of *O. annularis* species complex were unable to complete gametogenesis (Szmant and Gassman, 1990). Compared to recovered colonies, bleached colonies had lower tissue biomass, lower carbon-to-nitrogen ratios, and reduced growth, indicating the energy reserves needed for successful reproduction were not available (Szmant and Gassman, 1990).

During the 1987 bleaching event, 90 percent of all *O. annularis* species complex colonies surveyed at 30 m in the Cayman Islands were bleached. Bleaching was less severe at 46 m with 14 percent of *O. annularis* species complex colonies bleached. Five months after bleaching was first observed in the Cayman Islands, 54 percent of bleached *O. annularis* species complex colonies had not recovered. *Orbicella annularis* species complex had the slowest recovery of the 28 coral species observed to bleach (Ghield and Smith, 1990).

In a 1995 bleaching event in Belize, *O. annularis* species complex was the most affected coral taxon with 76 percent of the 2,126 surveyed colonies affected. Seven percent of the 904 colonies surveyed six months after the bleaching event remained bleached. Twenty-six percent of tagged *O. annularis* species complex colonies (n=19) exhibited partial mortality due to bleaching or post-bleaching infection by black band disease (McField, 1999).

In 20 surveys across 302 sites throughout the wider Caribbean, *O.*

*annularis* species complex and *Agaricia tenuifolia* were the taxa most impacted by the 1998 bleaching event (Ginsburg and Lang, 2003; Kramer, 2003). Subsequent disease outbreaks were also recorded in *O. annularis* and *O.*

*faveolata* off Curaçao, the Cayman Islands, Costa Rica, and some of the Virgin Islands after the bleaching event. Bleaching and disease related mortality heavily impacted the *O. annularis* species complex (Ginsburg and Lang, 2003).

During the 2005 bleaching event, approximately 70 percent of *O. annularis* species complex colonies bleached both in sites less than 10 m in depth and in sites greater than 15 m in depth on the west and southwest coasts of Barbados (Oxenford *et al.*, 2008). Bleaching was observed in 2005 at 86 of 94 sites (91 percent) surveyed in Buck Island Reef, U.S. Virgin Islands. Ninety-four percent of the cover of *O. annularis* species complex bleached (Clark *et al.*, 2009).

The 2005 bleaching event resulted in a 51 percent decrease in the cover of *O. annularis* species complex at five sites in the U.S. Virgin Islands between 2005 and 2007. Bleaching occurred in 16 of the 21 species of coral at the five sites with maximum tissue area bleached between 98 to 99.5 percent for the *O. annularis* species complex. Mortality after the bleaching event occurred primarily from a subsequent regional outbreak of coral disease, predominantly white plague, not the bleaching itself. The highest rate of mortality of the 19 species affected by the white plague was the *Orbicella annularis* species complex with 94.5 percent of disease lesions occurring on *Orbicella annularis* species complex. Total coral cover declined from 21 percent to 10 percent, and species-specific changes in coral cover affected the relative abundance of coral species on the reef. Overall relative abundance of *O. annularis* species complex declined from an initial average of 79 to 59 percent of live coral cover (Miller *et al.*, 2009).

Stratified random surveys on back-reefs and fore-reefs between one and 30 m depth off Puerto Rico (Mona and Desecho Islands, La Parguera, Mayaguez, Boqueron, and Rincon) in 2005 and 2006 revealed bleaching was most severe in *O. annularis* species complex with 94 percent of colonies bleached. After bleaching, a disease outbreak occurred, and *O. annularis* species complex suffered extensive partial and total mortality. Coral cover declined between 40 and 60 percent and was primarily driven by mortality of *O. annularis* species complex.

Additionally, the severe tissue loss and prolonged bleaching stress resulted in reproductive collapse of *O. annularis* species complex during the 2006 mass spawning cycle (Waddell and Clarke, 2008).

The 2005 bleaching affected greater than 95 percent of *O. annularis* species complex in Mona and Desecho Islands, Puerto Rico and was followed by a disease outbreak that both caused extensive mortality (Bruckner and Hill, 2009). A study of 36 sites across six countries (Grenada, Curaçao, Panamá, Puerto Rico, Cayman Islands, and Bermuda) and three depth habitats (less than 4 m, 5 to 12 m, and greater than 15 m) found a significant correlation between the 2005 bleaching and prevalence of yellow band disease and white plague in *O. annularis* species complex (Croquer and Weil, 2009). *Orbicella annularis* species complex bleached at all depths surveyed in Grenada (23 to 52 percent of colonies), Puerto Rico (21 to 40 percent), and Cayman Islands (16 to 44 percent). The species complex did not experience bleaching in Curacao or Bermuda, both locations reported very low bleaching across all genera examined (Croquer and Weil, 2009). Bleaching of *O. annularis* species complex varied by depth in Panama with bleaching occurring in 11 percent of colonies in depths less than 4 m and in 15 percent of colonies in depths between 5 and 12 m, but no bleaching occurred in deep depths greater than 15 m (Croquer and Weil, 2009). Smith *et al.* (2013b) described species responses to the 2005 and 2010 bleaching events in St. Thomas, St. Croix, and St. John, U.S. Virgin Islands. The response of the *O. annularis* species complex (mostly *O. faveolata* and *O. franksi* with the likelihood of small numbers of *O. annularis*) to the 2005 bleaching event was high to moderate initial response of bleaching prevalence, high disease prevalence, high mortality, a large decline in coral cover, and increasing or stable colony abundance. Average bleaching was 66 percent, and paling was 27 percent in 2005. Disease prevalence in *O. annularis* complex was 17 percent after the 2005 bleaching event. In the milder 2010 bleaching event, 35 percent of *O. annularis* species complex colonies bleached, and 47 percent of *O. annularis* species complex colonies paled. Less than one percent of *O. annularis* species complex colonies suffered total mortality, but percent cover decreased from seven percent cover of *O. annularis* species complex in 2005 before bleaching to less than three percent in 2007. By 2010, there was a slight increase in percent cover to

about four percent. *Orbicella annularis* species complex lost a large proportion of colonies in the largest size class and showed a significant increase in colony abundance, likely due to the increase in abundance of colonies in smaller size classes resulting from partial mortality of larger colonies.

Van Woesik *et al.* (2012) developed a coral resiliency index based on biological traits and processes to evaluate extinction risk due to bleaching. Evaluations were performed at the genus level, but genera were separated between the Caribbean and Indo-Pacific. They rated the resiliency score for the *O. annularis* species complex as four out of a range of -6 to 7 observed in other coral genera. Less than or equal to -3 was considered highly vulnerable to extinction, and greater than or equal to 4 was considered highly tolerant. Thus, *O. annularis* species complex was rated as highly tolerant. However, Smith *et al.* (2013b) concluded that large favids, such as the *O. annularis* species complex, seem very susceptible to long-term population declines because of their poor response to stress response when bleaching, disease, and mortality were considered. The *O. annularis* species complex was found to be likely less equipped to recovery after bleaching because they tend to grow slowly, have lower fecundity, and are more susceptible to mortality when small (Smith *et al.*, 2013b). While the van Woesik *et al.* (2012) study was in the SIR, the findings specific to *Orbicella* were not included. The public comments indicated the results of this study should be considered in the listing status of the three species in the *Orbicella* species complex.

All sources of information are used to describe *Orbicella*'s susceptibility to ocean warming as follows. The *O. annularis* species complex is highly susceptible to ocean warming. Bleaching often occurs in 76 to 94 percent of *O. annularis* species complex colonies during bleaching events, and *Orbicella* spp. are one of the taxa most affected by high temperatures. Colonies in deeper water have been reported to bleach less severely. Recovery from bleaching can take longer for the species complex than for other coral species, and prolonged stress from bleaching has been cited as a possible reason for reproductive failure following bleaching events. Mortality from temperature anomalies is often due to subsequent disease outbreaks. Thus, we conclude that the *O. annularis* species complex is highly susceptible to ocean warming.

The SRR and SIR provided the following information on *Orbicella*'s

susceptibility to acidification. The only study conducted regarding the impact of acidification on this genus is a field study that did not find any change in *O. faveolata* calcification in field-sampled colonies from the Florida Keys up through 1996. Preliminary experiments testing effects of acidification on fertilization and settlement success of *O. annularis* species complex show results that are consistent with the significant impairments demonstrated for *A. palmata*.

The public comments did not provide new or supplemental information on the susceptibility of the *Orbicella* species complex to acidification. Supplemental information we found on the susceptibility of the *Orbicella* species complex to acidification includes the following. In laboratory experiments, reproduction of *O. faveolata* was negatively impacted by increasing carbon dioxide, and impairment of fertilization was exacerbated at lower sperm concentrations (Albright, 2011b). Fertilization success was reduced by 25 percent at 529  $\mu\text{atm}$  (43 percent fertilization) and 40 percent at 712  $\mu\text{atm}$  (34 percent fertilization) compared to controls at 435  $\mu\text{atm}$  (57 percent fertilization; Albright, 2011a). Additionally, growth rate of *O. faveolata* was reduced under lower pH conditions (7.6) compared to higher pH conditions (8.1) after 120 days of exposure (Hall *et al.*, 2012).

All sources of information are used to describe *Orbicella*'s susceptibility to acidification as follows. Laboratory studies indicate that *Orbicella* is susceptible to ocean acidification both through reduced fertilization of gametes and reduced growth of colonies. Thus, we conclude that the *Orbicella* species complex is highly susceptible to ocean acidification.

The SRR and SIR provided the following information on *Orbicella*'s susceptibility to disease. White plague and yellow band (also called yellow blotch) disease have caused profound population decline of the *Orbicella annularis* species complex both with and without prior bleaching.

The public comments did not provide new or supplemental information on the susceptibility of *Orbicella* spp. to disease. Supplemental information we found on *Orbicella*'s susceptibility to disease confirms and expands the information in the SRR and SIR. *Orbicella* spp. are susceptible to black band disease and dark spot syndrome (Alcolado *et al.*, 2010). Additionally, an unknown disease was observed in the Red Hind Marine Conservation District in the U.S. Virgin Islands and affected 39 percent of *O. annularis* species

complex colonies (Smith *et al.*, 2010). White plague is one of the most aggressive coral diseases in the Caribbean with progression rates of 1 to 10 cm per day (Bruckner and Hill, 2009). Tissue loss from yellow band disease is slow, averaging 0.5 to 1 cm per month, though tissue loss can be significant over the long term since colonies can remain infected for years and can have multiple lesions per colony (Bruckner and Bruckner, 2006b).

In the Florida Keys, the prevalence of white plague increased between 1996 and 2002. No *O. annularis* species complex colonies with white plague were reported within monitoring stations in 1996, but infected colonies appeared in 32 stations in 2002 (Waddell, 2005). *Orbicella annularis* species complex had the highest prevalence (up to 12 percent) of the 21 species affected by white plague in Puerto Rico between 1998 and 2008 (Bruckner and Hill, 2009). In Mexico, *O. annularis* species complex had the highest disease prevalence in surveys during 2004 (27 percent, Ward *et al.*, 2006). Surveys in four locations (Netherlands Antilles, Grenada, Turks and Caicos, and U.S. Virgin Islands) between 1997 and 1998 revealed that prevalence of yellow band in *O. annularis* species complex ranged from 18 to 91 percent.

Tagged colonies with yellow band disease in Puerto Rico lost an average of 32 percent of their tissue over four years, and the percent of partial mortality appeared to increase with colony size (Bruckner and Bruckner, 2006b). Eight percent of infected colonies died completely (most were 50 cm or less in size), and larger colonies lost between 60 and 85 percent of their tissue (Bruckner and Bruckner, 2006b). Eighty-five percent of colonies with yellow band disease tagged in 1999 still had active signs of the disease in 2003 (Bruckner and Bruckner, 2006b). In 1999, yellow band disease affected up to 50 percent of all *O. annularis* species complex colonies at permanent sites in Puerto Rico, including many of the largest (2 to 3 m diameter and height) and presumably oldest colonies (Waddell and Clarke, 2008).

In Curacao, yellow band disease affected from three to 49 percent of all *O. annularis* species complex colonies within transects conducted on western reefs between 1997 and 2005. The highest prevalence of yellow band disease occurred in 1997 and 1998. Thirty-one to 49 percent of *O. annularis* species complex colonies were affected in eastern Curacao, and 24 percent were affected in western Curacao. The numbers of new infections declined

from 2000 to 2005. Yellow band disease affected larger corals more frequently than small corals. Over 21 percent of the colonies tagged with yellow band disease between 1997 and 1999 were still infected in 2005. Of the remainder, 44 percent died, 2 percent were affected by other diseases, and 32 percent no longer had signs of yellow band disease but had large amounts (most greater than 90 percent) of partial mortality (Bruckner and Bruckner, 2006a).

Disease prevalence in *O. annularis* species complex (*O. annularis* and *O. faveolata*) at three reefs off Mexico increased from between zero and four percent in 1996 and 1998 to between 26 and 37 percent in 2001. The increase was due to the proliferation of yellow band disease, though black band disease and white plague were also present. Partial mortality also increased over this same period from 20 to 35 percent of *O. annularis* species complex colonies at one site and from 35 to 52 percent at another (Jordan-Dahlgren *et al.*, 2005).

At 253 sites surveyed in 2009 in St. Croix and St. John, U.S. Virgin Islands and La Parguera, Puerto Rico, the average number of healthy *O. annularis* species complex colonies was 182 ( $\pm$  33 SE) per 100 m<sup>2</sup>. Yellow band was present on an average of about one percent of colonies (Muller and van Woesik, 2012).

All sources of information are used to describe *Orbicella*'s susceptibility to disease as follows. Disease can affect a large proportion of the *Orbicella* spp. population (3 to 91 percent), particularly during outbreaks following bleaching events, and can cause extensive mortality. Partial mortality can be high (32 to greater than 90 percent) and can result in multiple ramets. White plague and yellow band disease have had the greatest effect and can disproportionately affect larger colonies in the species complex. Total colony mortality is less likely for larger colonies than for smaller colonies, and partial mortality can lead to changes in colony size distribution as observed in Puerto Rico, U.S. Virgin Islands, and a study in Bahamas, Bonaire, Cayman Islands, and St. Kitts and Nevis. Thus, we conclude that the *O. annularis* species complex is highly susceptible to disease.

The SIR and SRR did not provide any information on the trophic effects of fishing on *Orbicella*. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the trophic effects of fishing on *Orbicella*. However, as described above in Caribbean Genera and Species—Introduction, due to the

level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. This effect coupled with *Orbicella*'s low recruitment rate indicates it likely has some susceptibility to the trophic effects of fishing. The available information does not support a more precise description of its susceptibility.

The SRR and SIR provided the following information on the susceptibility of *Orbicella* to sedimentation. *Orbicella* has shown a decline in growth at sediment impacted sites in Puerto Rico and during periods of construction in Aruba. Along a gradient of continental influence in the southern Gulf of Mexico, density and calcification rate of *O. annularis* decreased with increasing turbidity and sedimentation while extension rate increased with increasing turbidity and sedimentation.

The public comments did not provide new or supplemental information on the susceptibility of *Orbicella* to sedimentation. Supplemental information we found on the susceptibility of the *Orbicella annularis* species complex confirms the information in the SRR and SIR. The *Orbicella annularis* species complex appears to be moderately capable of removing sediment from the colony surface. Colonies receiving single applications of 200 or 400 mg sediment per cm<sup>2</sup> showed no evidence of damage while 800 mg per cm<sup>2</sup> caused mortality (Rogers, 1983). Sedimentation has been found to negatively affect *O. annularis* species complex primary production, growth rates, and abundance (Pastorok and Bilyard, 1985). An observed difference in average colony size at two sites in Puerto Rico led Loya (1976) to conclude turbidity negatively affects growth of *O. annularis* species complex since colony size was half as large at the sediment-impacted site (23 cm versus 9 cm).

All sources of information are used to describe *Orbicella*'s susceptibility to sedimentation as follows. Although the species complex is moderately capable of removing sediment from the colony surface, sedimentation negatively affects primary production, growth rates, calcification, colony size, and abundance. Thus, we conclude that the *O. annularis* species complex is highly susceptible to sedimentation.

The SRR and SIR provided the following information on the susceptibility of *Orbicella* to nutrient enrichment. *Orbicella* had an increasing growth rate with improving environmental conditions in Barbados.

Additionally, decreasing growth rate of *Orbicella* over a 30-year period was attributed to deterioration of water quality.

The public comments did not provide new or supplemental information on the susceptibility of *Orbicella* to nutrient enrichment. Supplemental information we found on the susceptibility of the *Orbicella* species complex confirms and expands the information in the SRR and SIR. Two growth forms of *O. annularis* species complex, columnar (likely *O. faveolata*) and lobate (likely *O. annularis*) were found to have increasing average growth rates with improving environmental conditions away from a eutrophication gradient in Barbados (Tomascik, 1990). Although nutrient concentration was negatively correlated with growth, suspended particulate matter resulting from eutrophication, rather than the nutrients themselves, was postulated to be the cause of observed decreased growth rates (Tomascik and Sander, 1985). A general pattern of decreasing growth rates of the columnar growth form between 1950 and 1983 may be directly related to the deterioration of water quality along the west coast of the island (Tomascik, 1990). Additionally, *Orbicella* spp. did not recruit to settlement plates on the most eutrophic reef, and recruitment of *Orbicella* spp. increased at sites with decreasing eutrophication along the eutrophication gradient (Tomascik, 1991). Field experiments indicate that nutrient enrichment significantly increases yellow band disease severity in *O. annularis* and *O. franksi* through increased tissue loss (Bruno *et al.*, 2003).

All sources of information are used to describe *Orbicella*'s susceptibility to nutrient enrichment as follows. The *Orbicella annularis* species complex is susceptible to nutrient enrichment through reduced growth rates, lowered recruitment, and increased disease severity. Thus, we conclude that the *O. annularis* species complex is highly susceptible to nutrient enrichment.

The SRR and SIR provided the following information on the susceptibility of *Orbicella* to predation. Predators of the *O. annularis* species complex include the corallivorous snail *Coralliophila abbreviata* and some species of parrotfish including *Sparisoma viride* and *S. aurofrenatum*. Additionally, damselfish remove live coral tissue to build algal gardens. The large decline of *Acropora* spp. in the Caribbean, likely resulted in greater impacts by damselfishes on other high-dimension corals, including the *O. annularis* species complex.

Public comments did not provide new or supplemental information on the susceptibility of *Orbicella* to predation. Supplemental information we found on the susceptibility of the *Orbicella* species complex includes the following. Surveys of six sites in Navassa found between zero and 33 percent of *O. annularis* species complex colonies (average 17 percent across all sites) were affected by *C. abbreviata* (Miller *et al.*, 2005). The *O. annularis* species complex was the preferred target of parrotfish across all reef habitats in a study on the Belize barrier reef. Incidence of parrotfish grazing was highest on *O. annularis* (over 55 percent of colonies), followed by *O. franksi* and *O. faveolata*, respectively (Rotjan, 2007). In most habitats, a few colonies of *Orbicella* spp. were more heavily grazed by parrotfishes, while the majority showed little or no parrotfish grazing (Rotjan and Lewis, 2006).

All sources of information are used to describe *Orbicella*'s susceptibility to predation as follows. The *O. annularis* species complex is susceptible to several predators. Current effects of predation appear to be low. Thus, we conclude the *O. annularis* species complex has low susceptibility to predation.

The SRR and SIR did not provide information on the effects of sea level rise on *Orbicella*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *Orbicella*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *Orbicella* has some susceptibility to sea level rise, but the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR provided the following information on the susceptibility of the *Orbicella* species complex to collection and trade. The *Orbicella* complex species have a very low occurrence in the CITES trade databases. Hence, collection and trade is not considered a significant threat to the *Orbicella annularis* complex species. The public comments did not provide new or supplemental information on the susceptibility of the *Orbicella* species complex to trade. Supplemental information we found on the susceptibility of species in the *Orbicella* complex to collection and trade is described in each of the individual species sections.

## Genus Conclusion

The *O. annularis* species complex is distributed throughout the Caribbean and occupies a variety of habitats across a large depth range, including mesophotic depths to 90 m. Over the last twenty years, major declines of approximately 50 to 95 percent have occurred. In addition, changes in size frequency distribution have sometimes accompanied decreases in cover, resulting in fewer large colonies that impact the buffering capacity of the species complex's life history strategy. Despite decline, the *O. annularis* species complex continues to be reported as the dominant coral taxon, sometimes at a lower percentage of the total coral cover.

The species complex has highly susceptibility to ocean warming, acidification, disease, sedimentation, and nutrients; some susceptibility to trophic effects of fishing and sea level rise; and low susceptibility to predation. Susceptibility to collection and trade is described in each of the individual species sections.

## *Orbicella faveolata*

### Introduction

The SRR and SIR provided the following information on *O. faveolata*'s morphology. *Orbicella faveolata* grows in heads or sheets, the surface of which may be smooth or have keels or bumps. The skeleton is much less dense than in the other two *Orbicella* species. Colony diameter can reach up to 10 m with a height of 4 to 5 m. The public comments did not provide new or supplemental information on *O. faveolata*'s morphology, and we did not find any new or supplemental information.

### Spatial Information

The SRR and SIR provided the following information on the distribution, habitat and depth range of *O. faveolata*. *Orbicella faveolata* occurs in the western Atlantic and throughout the Caribbean, including Bahamas, Flower Garden Banks, and the entire Caribbean coastline. There is conflicting information on whether or not it occurs in Bermuda. *Orbicella faveolata* has been reported in most reef habitats and is often the most abundant coral between 10 and 20 m in fore-reef environments. The depth range of *O. faveolata* has been reported as 0.5 to 40 m, though the species complex has been reported to depths of 90 m, indicating *O. faveolata*'s depth distribution is likely deeper than 40 m. *Orbicella* species are a common, often dominant component of Caribbean mesophotic

reefs, suggesting the potential for deep refugia for *O. faveolata*.

The public comments did not provide new or supplemental information on *O. faveolata*'s distribution, habitat, or depth range. Supplemental information we found includes the following. Veron (2014) confirmed the occurrence of *O. faveolata* in five out of his 11 ecoregions in the west Atlantic and greater Caribbean known to contain corals and strongly predicted its presence in an additional three ecoregions (off Colombia and Venezuela; Jamaica and Cayman Islands; and Florida and the Bahamas). Many studies have confirmed the presence of *O. faveolata* in these additional three ecoregions (Bayraktarov *et al.*, 2012; Bruckner, 2012a; Burman *et al.*, 2012). The ecoregions where Veron (2014) reported the absence of *O. faveolata* are off the coasts of Brazil, Bermuda, and the southeastern U.S. north of southern Florida (Veron, 2014). Smith (2013) reported that *O. faveolata* is found in the U.S. Virgin Islands across all depths to about 45 m.

### Demographic Information

The SRR and SIR provided the following information on *O. faveolata*'s abundance and population trends. *Orbicella faveolata* is considered common.

The public comments did not provide new or supplemental information on *O. faveolata*'s population trends but provided the following supplemental information on *O. faveolata*'s abundance. Extrapolated population estimates from stratified random samples in the Florida Keys were  $39.7 \pm 8$  million (SE) colonies in 2005,  $21.9 \pm 7$  million (SE) colonies in 2009, and  $47.3 \pm 14.5$  million (SE) colonies in 2012. The greatest proportion of colonies tended to fall in the 10 to 20 cm and 20 to 30 cm size classes in all survey years, but there was a fairly large proportion of colonies in the greater than 90 cm size class. Partial mortality of the colonies was between 10 and 60 percent surface across all size classes. In the Dry Tortugas, Florida, *O. faveolata* ranked seventh most abundant out of 43 coral species in 2006 and fifth most abundant out of 40 in 2008. Extrapolated population estimates were  $36.1 \pm 4.8$  million (SE) colonies in 2006 and  $30 \pm 3.3$  million (SE) colonies in 2008. The size classes with the largest proportion of colonies were 10 to 20 cm and 20 to 30 cm, but there was a fairly large proportion of colonies in the greater than 90 cm size class. Partial mortality of the colonies ranged between approximately two percent and 50 percent. Because these population abundance estimates are based on

random surveys, differences between years may be attributed to sampling effort rather than population trends (Miller *et al.*, 2013).

Supplemental information we found on *O. faveolata*'s abundance and population trends includes the following. In a survey of 31 sites in Dominica between 1999 and 2002, *O. faveolata* was present at 80 percent of the sites at one to ten percent cover (Steiner, 2003). In a 1995 survey of 16 reefs in the Florida Keys, *O. faveolata* ranked as the coral species with the second highest percent cover (Murdoch and Aronson, 1999). On 84 patch reefs (3 to 5 m depth) spanning 240 km in the Florida Keys, *O. faveolata* was the third most abundant coral species comprising seven percent of the 17,568 colonies encountered and was present at 95 percent of surveyed reefs between 2001 and 2003 (Lirman and Fong, 2007). In surveys of 280 sites in the upper Florida Keys in 2011, *O. faveolata* was present at 87 percent of sites visited (Miller *et al.*, 2011b). In 2003 on the East Flower Garden Bank, *O. faveolata* comprised ten percent of the 76.5 percent coral cover on reefs 32 to 40 m, and partial mortality due to bleaching, disease, and predation were rare at monitoring stations (Precht *et al.*, 2005).

Colony density ranges from approximately 0.1 to 1.8 colonies per 10 m<sup>2</sup> and varies by habitat and location. In surveys along the Florida reef tract from Martin County to the lower Florida Keys, density of *O. faveolata* was approximately 1.6 colonies per 10 m<sup>2</sup> (Wagner *et al.*, 2010). On remote reefs off southwest Cuba, density of *O. faveolata* was  $0.12 \pm 0.20$  (SD) colonies per 10 m transect on 38 reef-crest sites and  $1.26 \pm 1.06$  colonies per 10 m transect on 30 reef-front sites (Alcolado *et al.* 2010). In surveys of 1,176 sites in southeast Florida, the Dry Tortugas, and the Florida Keys between 2005 and 2010, density of *O. faveolata* ranged between 0.17 and 1.75 colonies per 10 m<sup>2</sup> and was highest on mid-channel reefs followed by offshore patch reefs and fore-reefs (Burman *et al.*, 2012). Along the east coast of Florida, density was highest in areas south of Miami at 0.94 colonies per 10 m<sup>2</sup> compared to 0.11 colonies per 10 m<sup>2</sup> in Palm Beach and Broward Counties (Burman *et al.*, 2012).

*Orbicella faveolata* is the sixth most abundant species by percent cover in permanent monitoring stations in the U.S. Virgin Islands. The species complex had the highest abundance and included all colonies where species identification was uncertain. Therefore, *O. faveolata* is likely more abundant. Population estimates in the 49 km<sup>2</sup> Red

Hind Marine Conservation District are at least 16 million colonies (Smith, 2013).

Population trend data exists for several locations. At nine sites off Mona and Desecheo Islands, Puerto Rico, no species extirpations were noted at any site over ten years of monitoring between 1998 and 2008 (Bruckner and Hill, 2009). Both *O. faveolata* and *O. annularis* sustained the large losses during the period. The number of colonies of *O. faveolata* decreased by 36 and 48 percent at Mona and Desecheo Islands, respectively (Bruckner and Hill, 2009). In 1998, 27 percent of all corals at six sites surveyed off Mona Island were *O. faveolata* colonies, but decreased to approximately 11 percent in 2008 (Bruckner and Hill, 2009). At Desecheo Island, 12 percent of all coral colonies were *O. faveolata* in 2000 compared to seven percent in 2008.

In a survey of 185 sites in five countries (Bahamas, Bonaire, Cayman Islands, Puerto Rico, and St. Kitts and Nevis) between 2010 and 2011, size of *O. faveolata* colonies was significantly greater than *O. franksi* and *O. annularis*. The total mean partial mortality of *O. faveolata* at all sites was 38 percent. The total live area occupied by *O. faveolata* declined by a mean of 65 percent, and mean colony size declined from 4005 cm<sup>2</sup> to 1413 cm<sup>2</sup>. At the same time, there was a 168 percent increase in small tissue remnants less than 500 cm<sup>2</sup>, while the proportion of completely live large (1,500 to 30,000 cm<sup>2</sup>) colonies decreased. *Orbicella faveolata* colonies in Puerto Rico were much larger and sustained higher levels of mortality compared to the other four countries. Colonies in Bonaire were also large but experienced much lower levels of mortality. Mortality was attributed primarily to outbreaks of white plague and yellow band disease, which emerged as corals began recovering from mass bleaching events. This was followed by increased predation and removal of live tissue by damselfish to cultivate algal lawns (Bruckner, 2012a).

All information on *O. faveolata*'s abundance and population trends can be summarized as follows. *Orbicella faveolata* is a common species throughout the greater Caribbean. Based on population estimates, there are at least tens of millions of colonies present in each of several locations including the Florida Keys, Dry Tortugas, and the U.S. Virgin Islands. Absolute abundance is higher than the estimate from these three locations given the presence of this species in many other locations throughout its range. Population decline has occurred over the past few decades with a 65 percent loss in *O. faveolata* cover across five countries. Losses of *O.*

*faveolata* from Mona and Desecheo Islands, Puerto Rico include a 36 to 48 percent reduction in abundance and a decrease of 42 to 59 percent in its relative abundance (*i.e.*, proportion relative to all coral colonies). High partial mortality of colonies has led to smaller colony sizes and a decrease of larger colonies in some locations such as the Bahamas, Bonaire, Puerto Rico, Cayman Islands, and St. Kitts and Nevis. Partial colony mortality is lower in some areas such as the Flower Garden Banks. We conclude that *O. faveolata* has declined but remains common and likely has at least tens of millions of colonies throughout its range. Additionally as discussed in the genus section, we conclude that the buffering capacity of *O. faveolata*'s life history strategy that has allowed it to remain abundant has been reduced by the recent population declines and amounts of partial mortality, particularly in large colonies.

#### Other Biological Information

The SRR and SIR provided the following information on *O. faveolata*'s life history. In many life history characteristics, including growth rates, tissue regeneration, and egg size, *O. faveolata* is considered intermediate between *O. annularis* and *O. franksi*. Spatial distribution may affect fecundity on the reef, with deeper colonies of *O. faveolata* being less fecund due to greater polyp spacing.

The public comments did not provide new or supplemental information on the life history of *O. faveolata*. Supplemental information we found on *O. faveolata*'s life history includes the following. Reported growth rates of *O. faveolata* range between 0.3 and 1.6 cm per year (Cruz-Piñón *et al.*, 2003; Tomascik, 1990; Villinski, 2003; Waddell, 2005). Graham and van Woeseik (2013) report that 44 percent of small colonies of *O. faveolata* in Puerto Morelos, Mexico, resulting from partial colony mortality produced eggs at sizes smaller than maturation. The number of eggs produced per unit area of smaller fragments was significantly less than in larger size classes. Szmant and Miller (2005) reported low post-settlement survivorship for *O. faveolata* transplanted to the field with only three to 15 percent remaining alive after 30 days. Post-settlement survivorship was much lower than the 29 percent observed for *A. palmata* after seven months (Szmant and Miller, 2005). Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The

classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Orbicella faveolata* was classified as a "generalist" species, thus likely less vulnerable to environmental stress.

The SRR and SIR provided the following other biological information on *O. faveolata*. Surveys at an inshore patch reef in the Florida Keys that experienced temperatures less than 18 degrees C for 11 days revealed species-specific cold-water susceptibility and survivorship. *Orbicella faveolata* was one of the more susceptible species with 90 percent of colonies experiencing total colony mortality, including some colonies estimated to be more than 200 years old (Kemp *et al.*, 2011). In surveys from Martin County to the lower Florida Keys, *O. faveolata* was the second most susceptible coral species experiencing an average of 37 percent partial mortality (Lirman *et al.*, 2011).

The public comments did not provide any new or supplemental biological information on *O. faveolata*. Supplemental biological information we found on *O. faveolata* includes the following. Samples (n = 182) of *O. faveolata* from the upper and lower Florida Keys and Mexico showed three well-defined populations based on five genetic markers, but the populations were not stratified by geography, indicating they were shared among the three regions (Baums *et al.*, 2010). Of ten *O. faveolata* colonies observed to spawn at a site off Bocas del Toro, Panama, colonies sorted into three spatially arranged genotypes (Levitán *et al.*, 2011).

*Orbicella faveolata* larvae are sensitive to ultraviolet radiation during the motile planula stage through the onset of larval competence (Aranda *et al.*, 2011). Of six Caribbean coral species exposed to high solar irradiation, *O. faveolata* and *Stephanocoenia intersepta* had the most severe decline in photochemical efficiency resulting in severe tissue loss and mortality (Fournie *et al.*, 2012).

Experiments exposing *O. faveolata* to high temperatures (up to 35 degrees C) revealed that the corals produced heat shock proteins at temperatures between 33 and 35 degrees C even for very short exposures (2 h) but did respond at temperatures between 27 and 31 degrees C when exposed from 2 hours to one week (Black *et al.*, 1995).

Thornhill *et al.* (2006) repeatedly sampled symbiont composition of colonies of six coral species in the Bahamas and the Florida Keys in 1998 and 2000 to 2004, during and after the 1997–98 bleaching event. Symbioses in *O. faveolata* remained stable at virtually

all sites in the Bahamas and the Florida Keys. Individual colonies usually showed fidelity over time to one particular *Symbiodinium* partner, and changing symbiont types was rare, thus indicating acclimation to warming temperatures may not occur by symbiont shuffling.

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *O. faveolata*'s vulnerabilities to threats as follows: High vulnerability to ocean warming, disease, acidification, sedimentation, and nutrient enrichment; moderate vulnerability to the trophic effects of fishing; and low vulnerability to sea level rise, predation, and collection and trade.

The SRR and SIR provided the following information on the susceptibility of *O. faveolata* to ocean warming. Recent work in the Mesoamerican reef system indicated that *O. faveolata* had reduced thermal tolerance in locations with increasing human populations and over time, implying increasing local threats. At sites in Navassa, *O. faveolata* and *Agaricia* spp. were the most susceptible to bleaching. Approximately 90 percent of *O. faveolata* colonies (n = 334) bleached at deeper sites (>18 m), and approximately 60 percent of *O. faveolata* colonies (n = 20) bleached at shallower sites (<10 m) in 2006. During a moderate bleaching event in Colombia in 2010, 100 percent of *O. faveolata* colonies bleached at a site in Gayraca Bay, and 50 percent of *O. faveolata* colonies were dead and completely overgrown by algae in 2011 (Bayraktarov *et al.*, 2012).

The public comments did not provide new or supplemental information on the susceptibility of *O. faveolata* to ocean warming. Supplemental information we found on the susceptibility of *O. faveolata* to ocean warming includes the following. Stratified random surveys on back-reefs and fore-reefs between one and 30 m depth off Puerto Rico (Mona and Desecho Islands, La Parguera, Mayaguez, Boqueron, and Rincon) in 2005 and 2006 revealed severe bleaching in *O. faveolata* with approximately 90 percent of colonies bleached (Waddell and Clarke, 2008). Surveys from 2005 to 2007 along the Florida reef tract from Martin County to the lower Florida Keys indicated that *O. faveolata* had the 13th highest bleaching prevalence out of 30 species observed to bleach (Wagner *et al.*, 2010). During a 2009 bleaching event on Little Cayman, of the ten coral species that bleached, *O. faveolata* had the third highest

bleaching prevalence with approximately 37 percent of colonies bleached (van Hooedonk *et al.*, 2012).

Coral cores from 92 colonies of *O. faveolata* from the Mesoamerican Reef around Belize and Honduras indicate that the bleaching event in 1998 was unprecedented in the prior century despite periods of higher temperatures and solar irradiance (Carilli *et al.*, 2010). The authors of the study concluded that bleaching in 1998 likely stemmed from reduced thermal tolerance due to the synergistic impacts of chronic local stressors stemming from land-based sources of pollution (Carilli *et al.*, 2010). Coral cores collected from four sites in Belize indicate that *O. faveolata* that experienced higher chronic stress were more severely affected by bleaching and had a much slower recovery after the severe 1998 bleaching event (Carilli *et al.*, 2009). Coral growth rates at sites with higher local anthropogenic stressors remained suppressed for at least eight years, while coral growth rates at sites with lower stress recovered in two to three years (Carilli *et al.*, 2009). Based on samples of *O. faveolata* and *O. franksi* collected from the Mesoamerican Barrier Reef, calcification of these two species is projected to cease at 35 degrees C in this location, even without an increase in acidification (Carricart-Ganivet *et al.*, 2012). Collections from Chinchorro Bank indicate that calcification of *O. faveolata* decreased 20 percent over the period of 1985 to 2009 where there was a 0.6 degree C increase in sea surface temperature (equivalent to 2.4 degrees C per century; Carricart-Ganivet *et al.*, 2012).

Polato *et al.* (2010) raised *O. faveolata* larvae derived from three to four colonies from Florida and Mexico under mean and elevated (1 to 2 degrees above summer mean) temperatures. Both locations had misshapen embryos at the elevated temperature, but the percentage was higher in the embryos from Florida. They found conserved and location-specific variation in gene expression in processes related to apoptosis (programmed cell death), cell structuring, adhesion and development, energy and protein metabolism, and response to stress.

Voolstra *et al.* (2009) exposed *O. faveolata* embryos to temperatures of 27.5, 29, and 31.5 degrees C directly after fertilization and measured differences in gene expression after 12 and 48 hours. They found a higher number of misshapen embryos after 12 hours at 29 and 31.5 degrees C in comparison to embryos kept at 27.5 degrees C. However, after 48 hours, the proportion of misshapen embryos

decreased for embryos kept at 29 and 31.5 degrees C, and increased for embryos kept at 27.5 degrees C. Increased temperatures may lead to oxidative stress, apoptosis, and a structural reconfiguration of the cytoskeletal network. However, embryos responded differently depending on exposure time and temperature level. Embryos showed expression of stress-related genes at a temperature of 29 degrees C but seemed to be able to counteract the initial response over time. Embryos at 31.5 degrees C displayed continuous expression of stress genes.

During the 2005 bleaching event, larger colonies of *O. faveolata* experienced more intensive bleaching than smaller colonies at inshore patch reefs of the Florida Keys (Brandt, 2009). *Orbicella faveolata* was one of the most affected species with approximately 80 percent of colonies (n = 77) bleached and, out of eight species that bleached, had the fourth highest bleaching prevalence (Brandt, 2009). *Orbicella faveolata* colonies with greater bleaching intensities later developed white plague disease (Brandt and McManus, 2009). White plague affected approximately ten percent of *O. faveolata* colonies and resulted in less than five percent tissue loss in all but two infected corals which experienced greater than five percent tissue loss (Brandt and McManus, 2009).

All sources of information are used to describe *O. faveolata*'s susceptibility to ocean warming as follows. *Orbicella faveolata* is highly susceptible to elevated temperatures. In lab experiments, elevated temperatures resulted in misshapen embryos and differential gene expression in larvae that could indicate negative effects on larval development and survival. Bleaching susceptibility is generally high with 37 to 100 percent of *O. faveolata* colonies reported to bleach during several bleaching events. Chronic local stressors can exacerbate the effects of warming temperatures, which can result in slower recovery from bleaching, reduced calcification, and slower growth rates for several years following bleaching. Additionally, disease outbreaks affecting *O. faveolata* have been linked to elevated temperature as they have occurred after bleaching events. We conclude that *O. faveolata* is highly susceptible to elevated temperature.

The SRR and SIR provided the following information on *O. faveolata*'s susceptibility to acidification. A field study did not find any change in *O. faveolata*'s calcification in field-

sampled colonies from the Florida Keys up through 1996.

The public comments did not provide new or supplemental information on the susceptibility of *O. faveolata* to acidification. Supplemental information we found on the susceptibility of *O. faveolata* to acidification includes the following. In laboratory experiments, reproduction of *O. faveolata* was negatively impacted by increasing CO<sub>2</sub>, and impairment of fertilization was exacerbated at lower sperm concentrations (Albright, 2011b). Fertilization success was reduced by 25 percent at 529  $\mu$ atm (43 percent fertilization) and 40 percent at 712  $\mu$ atm (34 percent fertilization) compared to controls at 435  $\mu$ atm (57 percent fertilization; Albright, 2011a). Additionally, growth rate of *O. faveolata* was reduced under lower pH conditions (7.6) compared to higher pH conditions (8.1) after 120 days of exposure (Hall *et al.*, 2012).

All sources of information are used to describe *O. faveolata*'s susceptibility to acidification as follows. Laboratory studies indicate that *O. faveolata* is susceptible to ocean acidification both through reduced fertilization of gametes and reduced growth of colonies. Thus, we conclude that *O. faveolata* is highly susceptible to ocean acidification.

The SRR and SIR did not provide any species-specific information on the susceptibility of *O. faveolata* to disease. The public comments also did not provide new or supplemental information on the susceptibility of *O. faveolata* to disease. Supplemental information we found on the susceptibility of *O. faveolata* to disease confirms the information on the *Orbicella* species complex and includes the following. Disease affected corals in Puerto Rico after the 2005 bleaching event, and *O. faveolata* was the species most affected (Bruckner and Hill, 2009). A 1998 outbreak of white plague on three surveyed reefs in St. Lucia affected 19 percent of *O. faveolata* colonies, and *O. faveolata* was the species most affected (Nugues, 2002). Larger colonies in St. Lucia were more likely to get infected, but they were less likely to suffer complete mortality (Nugues, 2002). Tissue mortality of marked *O. faveolata* colonies was 51 percent, and no colonies showed regrowth during the 8 month study period (Nugues, 2002). Disease surveys conducted between August and December 1999 at 19 reef sites from six geographic areas across the wider Caribbean (Bermuda, Puerto Rico, Bonaire, Venezuela, Colombia, and Jamaica) revealed that *O. faveolata* showed the second highest incidence of

disease at 4.7 to 10.4 percent across geographic locations (Weil *et al.*, 2002).

Surveys at five sites along the west coast of Dominica between 2000 and 2002 revealed that *O. faveolata* was one of the species most susceptible to disease. Of the 12 species infected by white plague in 2000, *O. faveolata* ranked second highest in disease prevalence (18.4 percent of infected colonies were *O. faveolata*); it ranked third in 2001 out of 14 species (12.7 percent) and second in 2002 out of 13 species (18.8 percent). In addition, white plague infected the larger size classes of *O. faveolata*. Although only one colony experienced total colony mortality, *O. faveolata* had the highest amount of tissue loss in each year and in the three years combined (Borger and Steiner, 2005).

Yellow band disease in *O. faveolata* increased in abundance between 1999 and 2004 on reefs near La Parguera and Desecheo and Mona Islands, Puerto Rico (Waddell, 2005). Yellow band disease mean lesion growth rates on *O. faveolata* in La Parguera, Puerto Rico had a significant positive correlation with mean yearly surface water temperatures between 1998 and 2010 (Burge *et al.*, 2014). In Curacao colonies of *O. faveolata* infected with yellow band disease lost 90 percent of their tissue between 1997 and 2005 (Bruckner and Bruckner, 2006a). Only the unaffected parts of colonies continued to grow, and only the smallest lesions caused by disease healed (Bruckner and Bruckner, 2006a). Partial mortality was higher in 2005 (average of 40 percent) than in 1998 (Bruckner and Bruckner, 2006a). Outbreaks of white plague occurred in 2001 and 2005 and infected *O. faveolata* and *O. annularis* with the highest frequency (Bruckner and Bruckner, 2006a).

Yellow band disease significantly affects *O. faveolata* reproductive output. Fecundity of diseased lesions was significantly lower than transition and healthy-looking tissues on diseased colonies. Diseased lesions had 99 percent fewer eggs compared to un-diseased control colonies. Fecundity in transition areas was 24 percent less than healthy-looking areas of diseased colonies and was significantly lower (50 percent) than in un-diseased control colonies. Healthy-looking tissues of diseased colonies had 27 percent lower fecundity compared to un-diseased control colonies. Furthermore, in colonies that had recovered from disease, small tissue remnants (less than 100 cm<sup>2</sup>) had 84 percent lower fecundity compared to un-diseased controls, and large tissue remnants (400 to 1000 cm<sup>2</sup>) had 64 percent lower

fecundity compared to un-diseased controls (Weil *et al.*, 2009).

All sources of information are used to describe *O. faveolata*'s susceptibility to disease as follows. *Orbicella faveolata* is often among the coral species with the highest disease prevalence and tissue loss. Outbreaks have been reported to affect ten to 19 percent of *O. faveolata* colonies, and yellow band disease and white plague have the greatest effect. Disease often affects larger colonies, and reported tissue loss due to disease ranges from five to 90 percent. Additionally, yellow band disease results in lower fecundity in diseased and recovered colonies of *O. faveolata*. Therefore, we conclude that *O. faveolata* is highly susceptible to disease.

The SIR and SRR did not provide any species-specific information on the trophic effects of fishing on *O. faveolata*. The public comments did not provide new or supplemental information, and we did not find supplemental information on the trophic effects of fishing on *O. faveolata*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. Thus, *O. faveolata* likely has some susceptibility to the trophic effects of fishing given its low recruitment rates. However, the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR did not provide species-specific information on the susceptibility of *O. faveolata* to sedimentation, and the public comments did not provide new or supplemental information on its susceptibility to this threat. Supplemental information we found confirms the information on the susceptibility of the *Orbicella* species complex to sedimentation and includes the following. In St. Lucia, rates of partial mortality of *O. annularis* and *O. faveolata* were higher close to river mouths where sediments were deposited than they were farther from the river mouths, indicating the sensitivity of these two species to sedimentation (Nugues and Roberts, 2003).

All sources of information are used to describe *O. faveolata*'s susceptibility to sedimentation as follows. Sedimentation can cause partial mortality of *O. faveolata*, and genus-level information indicates that sedimentation negatively affects primary production, growth rates, calcification, colony size, and

abundance. Therefore, we conclude that *O. faveolata* is highly susceptible to sedimentation.

The SRR, SIR, and public comments did not provide information on the susceptibility of *O. faveolata* to nutrient enrichment, and we did not find any new or supplemental information on the susceptibility of *O. faveolata* to nutrient enrichment.

All sources of information are used to describe *O. faveolata*'s susceptibility to nutrient enrichment as follows.

Although there is no species-specific information, the *Orbicella* species complex is susceptible to nutrient enrichment through reduced growth rates, lowered recruitment, and increased disease severity. Therefore, based on genus-level information, we conclude that *O. faveolata* is likely highly susceptible to nutrient enrichment.

The SRR and SIR provided the following information on the susceptibility of *O. faveolata* to predation. Under laboratory conditions, black band disease was transmitted to healthy *O. faveolata* fragments in the presence of the butterflyfish *Chaetodon capistratus* but not in aquaria without the fish present, suggesting that the fish acts as a disease vector (Aeby and Santavy, 2006).

The public comments did not provide new or supplemental information on the susceptibility of *O. faveolata* to predation. Supplemental information we found on the susceptibility of *O. faveolata* to predation includes the following. In surveys of the Florida Keys in 2012, two percent of *O. faveolata* colonies were affected by predation by the corallivorous snail *C. abbreviata* (Miller *et al.*, 2013). Parrotfish consume *O. annularis* and *O. faveolata* more intensively than other coral species, but tissue regeneration capabilities appear to be high enough to counterbalance loss from predation (Mumby, 2009).

All sources of information are used to describe *O. faveolata*'s susceptibility to predation as follows. *Orbicella faveolata* is affected by a number of predators, but losses appear to be minimal. We conclude that *O. faveolata* has low susceptibility to predation.

The SRR and SIR did not provide information on the effects of sea level rise on *O. faveolata*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *O. faveolata*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *O. faveolata* has some susceptibility to sea level rise, but the

available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR did not provide species-specific information on the susceptibility of *O. faveolata* to collection and trade, and the public comments did not provide new or supplemental information on its susceptibility to this threat. Supplemental information we found confirms the information in the SRR and SIR that collection and trade is not a significant threat for the *Orbicella* species complex. Over the last decade, collection and trade of this species has been primarily for scientific research rather than commercial purposes. Gross exports for collection and trade of *O. faveolata* between 2000 and 2012 averaged 271 specimens (data available at <http://trade.cites.org>). We conclude that *O. faveolata* has low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanism or conservation efforts for *O. faveolata*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *O. faveolata* occurs in five Atlantic ecoregions, and studies and observations have confirmed the presence of *O. faveolata* in an additional three ecoregions (Burman *et al.*, 2012). These eight ecoregions encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Caribbean Territories and possibly Bermuda), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *O. faveolata*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as the percentages of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent

limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *O. faveolata* are reef fishing regulations and area management for protection and conservation. However, half of the reef fishing regulations are limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *O. faveolata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the extinction risk for *O. faveolata* are its extremely low productivity (growth and recruitment), documented dramatic recent declines, and its restriction to the highly disturbed/degraded wider Caribbean region.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *O. faveolata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. The species has undergone major declines mostly due to warming-induced bleaching and disease. There is evidence of synergistic effects of threats for this species including disease outbreaks following

bleaching events and reduced thermal tolerance due to chronic local stressors stemming from land-based sources of pollution. *Orbicella faveolata* is highly susceptible to a number of threats, and cumulative effects of multiple threats have likely contributed to its decline and exacerbate vulnerability to extinction. Despite high declines, the species is still common and remains one of the most abundant species on Caribbean reefs. Its life history characteristics of large colony size and long life span have enabled it to remain relatively persistent despite slow growth and low recruitment rates, thus moderating vulnerability to extinction. However, the buffering capacity of these life history characteristics is expected to decrease as colonies shift to smaller size classes as has been observed in locations in its range. Its absolute population abundance has been estimated as at least tens of millions of colonies in each of several locations including the Florida Keys, Dry Tortugas, and the U.S. Virgin Islands and is higher than the estimate from these three locations due to the occurrence of the species in many other areas throughout its range. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *O. faveolata* is limited to an area with high, localized human impacts and predicted increasing threats. Its depth range of 0.5 to at least 40 m, possibly up to 90 m, moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower temperatures than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. *Orbicella faveolata* occurs in most reef habitats, including both shallow and mesophotic reefs, which moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance, life history characteristics, and depth distribution, combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the threats are non-uniform, and there will likely be a large number of colonies that are either not exposed

or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *O. faveolata* was proposed for listing as endangered because of: High vulnerability to ocean warming (E), disease (C), and ocean acidification (E); high vulnerability to sedimentation (A and E) and nutrient over-enrichment (A and E); decreasing trend in abundance (E); low relative recruitment rate (E); moderate overall distribution (based on narrow geographic distribution and wide depth distribution) (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *O. faveolata* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of the buffering capacity of this species' spatial and demographic traits, and the best available information above on *O. faveolata*'s spatial structure, demography, threat susceptibilities, and management. This combination of factors indicates that *O. faveolata* is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Orbicella faveolata* is highly susceptible to ocean warming (ESA Factor E), disease (C), ocean acidification (E), sedimentation (A, E), and nutrients (A, E) and susceptible to trophic effects of fishing (A). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address global threats (D);

(2) *Orbicella faveolata* is geographically located in the highly disturbed Caribbean where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future;

(3) *Orbicella faveolata* has experienced substantial declines in abundance and percent cover over the past two decades; and

(4) *Orbicella faveolata*'s slow growth rate and low sexual recruitment limit its capacity for recovery from threat-induced mortality events throughout its range over the foreseeable future.

Additionally, shifts to smaller size classes via fission and partial mortality of older, larger colonies, have reduced the buffering capacity of *O. faveolata*'s life history strategy.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range, and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *O. faveolata*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *Orbicella faveolata*'s distribution within the Caribbean increases its risk of exposure to threats as described above, its known depth distribution is between 0.5 and 45 m, with occurrence by the complex as deep as 90 m, and its habitat includes various shallow and mesophotic reef environments. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) Although *O. faveolata*'s abundance has declined, it still has a common occurrence and remains one of the most dominant corals in the Caribbean. Its absolute abundance is at least tens of millions of colonies based on estimates from three locations. Absolute abundance is higher than estimates from these locations since it occurs in many other locations throughout its range. This absolute abundance allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from

environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, multitudes of conservation efforts are already broadly employed that are likely benefiting *O. faveolata*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

#### *Orbicella franksi*

##### Introduction

The SRR and SIR provided the following information on *O. franksi*'s morphology. *Orbicella franksi* is distinguished by large, unevenly arrayed polyps that give the colony its characteristic irregular surface. Colony form is variable, and the skeleton is dense with poorly developed annual bands. Colony diameter can reach up to 5 m with a height of up to 2 m. The public comments did not provide new or supplemental information on *O. franksi*'s morphology, and we did not find any new or supplemental information.

##### Spatial Information

The SRR and SIR provided the following information on *O. franksi*'s distribution, habitat, and depth range. *Orbicella franksi* is distributed in the western Atlantic and throughout the Caribbean Sea including in the Bahamas, Bermuda, and the Flower Garden Banks. *Orbicella franksi* tends to have a deeper distribution than the other two species in the *Orbicella* species complex.

It occupies most reef environments and has been reported from water depths ranging from 5 to 50 m, with the species complex reported to 90 m. *Orbicella* species are a common, often dominant, component of Caribbean mesophotic reefs, suggesting the potential for deep refugia for *O. franksi*.

The public comments did not provide new or supplemental information on *O. franksi*'s distribution, habitat, or depth range. We did not find new or

supplemental information on *O. franksi*'s habitat or depth range. Supplemental information we found on *O. franksi*'s distribution includes the following. Veron (2014) confirmed the occurrence of *O. franksi* in six out of his 11 ecoregions in the western Atlantic and greater Caribbean known to contain corals and strongly predicted its presence in an additional three ecoregions (off Colombia/Venezuela, Cuba/Cayman Islands, and Jamaica). Other studies confirm the presence of *O. franksi* in three other ecoregions (Alcolado *et al.*, 2010; Bayraktarov *et al.*, 2012; Bruckner, 2012c; Weil *et al.*, 2002). The two ecoregions where *O. franksi* has not been found are off the coasts of Brazil and the southeastern U.S. north of southern Florida (Veron, 2014).

##### Demographic Information

The SRR and SIR provided the following information on *O. franksi*'s abundance and population trends. *Orbicella franksi* is reported as common.

The public comments provided the following supplemental information on *O. franksi*'s abundance and population trends. In surveys throughout the Florida Keys, *O. franksi* in 2005 ranked 26th most abundant out of 47 coral species, 32nd out of 43 in 2009, and 33rd out of 40 in 2012. Extrapolated population estimates from stratified random surveys were  $8.0 \pm 3.5$  million (SE) colonies in 2005,  $0.3 \pm 0.2$  million (SE) colonies in 2009, and  $0.4 \pm 0.4$  million (SE) colonies in 2012. The authors note that differences in extrapolated abundance between years were more likely a function of sampling effort rather than an indication of population trends. In 2005, the greatest proportions of colonies were in the smaller size classes of 10 to 20 cm and 20 to 30 cm. Partial colony mortality ranged from zero to approximately 73 percent and was generally higher in larger colonies (Miller *et al.*, 2013).

In the Dry Tortugas, Florida, *O. franksi* ranked fourth highest in abundance out of 43 coral species in 2006 and eighth out of 40 in 2008. Extrapolated population estimates were  $79 \pm 19$  million (SE) colonies in 2006 and  $18.2 \pm 4.1$  million (SE) colonies in 2008. The authors note the difference in estimates between years was more likely a function of sampling effort rather than population decline. In the first year of the study (*i.e.*, 2006), the greatest proportion of colonies were in the size class 20 to 30 cm with twice as many colonies as the next most numerous size class, and a fair number of colonies in the largest size class of greater than 90

cm. Partial colony mortality ranged from approximately ten to 55 percent. Two years later in 2008 no size class was found to dominate, and proportion of colonies in the medium to large size classes (60 to 90 cm) appeared to be less than in 2006. The number of colonies in the largest size class of greater than 90 cm remained consistent. Partial colony mortality ranged from approximately 15 to 75 percent (Miller *et al.*, 2013).

Supplemental information we found on *O. franksi*'s abundance and population trends includes the following. In a 1995 survey of 16 reefs in the Florida Keys, *O. franksi* has the highest percent cover of all species (Murdoch and Aronson, 1999). In a survey of 31 sites in Dominica between 1999 and 2002, *O. franksi* was present in seven percent of the sites at less than one percent cover (Steiner, 2003). In 2003 on the east Flower Garden Bank, *O. franksi* comprised 46 percent of the 76.5 percent coral cover on reefs 32 to 40 m in depth, and partial coral mortality due to bleaching, disease, and predation was rare in survey stations (Precht *et al.*, 2005).

Reported density is variable by location and habitat and is reported to range from 0.02 to 1.05 colonies per 10 m<sup>2</sup>. In surveys of 1,176 sites in southeast Florida, the Dry Tortugas, and the Florida Keys between 2005 and 2010, density of *O. franksi* ranged between 0.04 and 0.47 colonies per 10 m<sup>2</sup> and was highest on the offshore patch reef and fore-reef habitats (Burman *et al.*, 2012). In south Florida, density was highest in areas south of Miami at 0.44 colonies per 10 m<sup>2</sup> compared to 0.02 colonies per 10 m<sup>2</sup> in Palm Beach and Broward Counties (Burman *et al.*, 2012). Along the Florida reef tract from Martin County to the lower Florida Keys, density of *O. franksi* was approximately 0.9 colonies per 10 m<sup>2</sup> (Wagner *et al.*, 2010). On remote reefs off southwest Cuba, colony density was  $0.083 \pm 0.17$  (SD) per 10 m transect on 38 reef-crest sites and  $1.05 \pm 1.02$  colonies per 10 m transect on 30 reef-front sites (Alcolado *et al.*, 2010). The number of *O. franksi* colonies in Cuba with partial colony mortality were far more frequent than those with no mortality across all size classes, except for one (*i.e.*, less than 50 cm) that had similar frequency of colonies with and without partial mortality (Alcolado *et al.*, 2010).

In the U.S. Virgin Islands, *O. franksi* is the second most abundant species by percent cover at permanent monitoring stations. However, because the species complex, which is the most abundant by cover, was included as a category when individual *Orbicella* species could not

be identified with certainty, it is likely that *O. franksi* is the most abundant. Population estimates of *O. franksi* in the 49 km<sup>2</sup> Red Hind Marine Conservation District are at least 34 million colonies (Smith, 2013).

Abundance in Curacao and Puerto Rico and appears to be stable over an eight to ten year period. In Curacao, abundance was stable between 1997 and 2005, with partial mortality similar or less in 2005 compared to 1998 (Bruckner and Bruckner, 2006a). Abundance was also stable between 1998–2008 at nine sites off Mona and Desecheo Islands, Puerto Rico. In 1998, 4 percent of all corals at six sites surveyed off Mona Island were *O. franksi* colonies in 1998 and approximately five percent in 2008; at Desecheo Island, about two percent of all coral colonies were *O. franksi* in both 2000 and 2008 (Bruckner and Hill, 2009).

On the other hand, colony size has decreased over the past several decades. A survey of 185 sites (2010 and 2011) in five countries (Bahamas, Bonaire, Cayman Islands, Puerto Rico, and St. Kitts and Nevis) reported the size of *O. franksi* and *O. annularis* colonies as significantly smaller than *O. faveolata*. The total mean partial mortality of *O. franksi* was 25 percent. Overall, the total live area occupied by *O. franksi* declined by a mean of 38 percent, and mean colony size declined from 1356 cm<sup>2</sup> to 845 cm<sup>2</sup>. At the same time there was a 137 percent increase in small tissue remnants less than 500 cm<sup>2</sup>, along with a decline in the proportion of large (1,500 to 30,000 cm<sup>2</sup>), completely alive colonies. Mortality was attributed primarily to outbreaks of white plague and yellow band disease, which emerged as corals began recovering from mass bleaching events. This was followed by increased predation and removal of live tissue by damselfish to cultivate algal lawns (Bruckner, 2012a).

All information on *O. franksi*'s abundance and population trends can be summarized as follows. Based on population estimates, there are at least tens of millions of colonies present in both the Dry Tortugas and U.S. Virgin Islands. Absolute abundance is higher than the estimate from these two locations given the presence of this species in many other locations throughout its range. The frequency and extent of partial mortality, especially in larger colonies of *O. franksi*, appear to be high in some locations such as Florida and Cuba, though other locations like the Flower Garden Banks appear to have lower amounts of partial mortality. A decrease in *O. franksi* percent cover by 38 percent, and a shift

to smaller colony size across five countries, suggest that population decline has occurred in some areas; colony abundance appears to be stable in other areas. We conclude that while population decline has occurred, *O. franksi* is still common with the number of colonies at least in the tens of millions. Additionally, as discussed in the genus section, we conclude that the buffering capacity of *O. franksi*'s life history strategy that has allowed it to remain abundant has been reduced by the recent population declines and amounts of partial mortality, particularly in large colonies.

#### Other Biological Information

The SRR and SIR provided the following information on *O. franksi*'s life history. The growth rate for *O. franksi* is reported to be slower, and spawning is reported to be about one to two hours earlier than *O. annularis* and *O. faveolata*.

The public comments did not provide new or supplemental information on *O. franksi*'s life history. Supplemental information we found on *O. franksi*'s life history includes the following. Of 361 colonies of *O. franksi* tagged in Bocas del Toro, Panama, larger colonies were noted to spawn more frequently than smaller colonies between 2002 and 2009 (Levitan *et al.*, 2011). Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Orbicella franksi* was classified as a "generalist" species, thus likely less vulnerable to environmental stress.

The SRR and SIR provided the following other biological information on *O. franksi*. Low tissue biomass can render specific colonies of *O. franksi* susceptible to mortality from stress events, such as bleaching or disease. This suggests that differential mortality among individuals, species, and reefs from stress events such as bleaching or disease may be at least partially a function of differential colony biomass (indicating overall coral health) as opposed to genetic or physiologic differences among corals or their symbionts.

In a 2010 cold-water event that affected south Florida, *O. franksi* ranked as the 14th most susceptible coral species out of 25 of the most abundant coral species. Average partial mortality was eight percent in surveys from Martin County to the lower Florida Keys after the 2010 cold-water event compared to 0.4 percent average

mortality during summer surveys between 2005 and 2009.

The public comments did not provide new or supplemental biological information on *O. franksi*. Supplemental biological information we found on *O. franksi* includes the following. Of 351 *O. franksi* colonies observed to spawn at a site off Bocas del Toro, Panama, 324 were unique genotypes. Over 90 percent of *O. franksi* corals on this reef were the product of sexual reproduction, and 19 genetic individuals had asexually propagated colonies made up of two to four spatially adjacent ramets each. Individuals within a genotype spawned more synchronously than individuals of different genotypes. Additionally, within 5m, colonies nearby spawned more synchronously than farther spaced colonies, regardless of genotype. At distances greater than 5m, spawning was random between colonies (Levitan *et al.*, 2011).

In a study of symbiont composition of repeatedly sampled colonies of six species in the Bahamas and the Florida Keys (1998, and 2000 to 2004), major changes in symbiont dominance over time were observed at certain Florida Keys reefs in *O. annularis* and *O. franksi*. Some colonies of *O. annularis* and *O. franksi* exhibited shifts in their associations attributed to recovery from the stresses of the 1997–98 bleaching event. Most transitions in symbiont identity ended in 2002, three to five years after the 1997–98 bleaching event (Thornhill *et al.*, 2006).

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *O. franksi*'s vulnerability to threats as follows: High vulnerability to ocean warming, disease, acidification, sedimentation, and nutrient enrichment; moderate vulnerability to the trophic effects of fishing; and low vulnerability to sea level rise, predation, and collection and trade.

The SRR and SIR did not provide species-specific information on the susceptibility of *O. franksi* to ocean warming. The public comments did not provide new or supplemental information on the susceptibility of *O. franksi* to ocean warming. Supplemental information we found on the susceptibility of *O. franksi* to ocean warming includes the following. A high percentage of *O. franksi* colonies experience bleaching during warm water temperature anomalies. Stratified random surveys on back-reefs and fore-reefs between one and 30 m depth off Puerto Rico (Mona and Desecheo Islands,

La Parguera, Mayaguez, Boqueron, and Rincon) in 2005 and 2006 revealed severe bleaching in *O. franksi* with approximately 90 percent of colonies bleached (Waddell and Clarke, 2008). Surveys from 2005 to 2007 along the Florida reef tract from Martin County to the lower Florida Keys indicated *O. franksi* had the tenth highest bleaching prevalence out of 30 species observed to bleach (Wagner *et al.*, 2010). During a moderate bleaching event in Colombia in 2010, 88 percent of *O. franksi* bleached, and 12 percent paled at a site in Gayraca Bay (Bayraktarov *et al.*, 2012). In 2011, 75 percent of *O. franksi* were dead and completely overgrown by algae (Bayraktarov *et al.*, 2012). Based on samples of *O. franksi* and *O. faveolata* collected from the Mesoamerican Barrier Reef, calcification of these two species is projected to cease at 35 degrees C in this location in the absence of acidification (Carricart-Ganivet *et al.*, 2012).

All sources of information are used to describe *O. franksi*'s susceptibility to ocean warming as follows. Available information indicates that *O. franksi* is highly susceptible to warming temperatures with a reported 88 to 90 percent bleaching frequency. Reported bleaching-related mortality from one study is high at 75 percent. There is indication that symbiont shuffling after bleaching in *O. franksi*. We conclude that *O. franksi* is highly susceptible to ocean warming.

The SRR and SIR did not provide any species-specific information on the susceptibility of *O. franksi* to acidification, and the public comments did not provide new or supplemental information on its susceptibility to this threat. We did not find any new or supplemental information on the susceptibility of *O. franksi* to acidification. Although there is no species-specific information on the susceptibility of *O. franksi* to ocean acidification, genus information indicates that the species complex has reduced growth and fertilization success under acidic conditions. Thus, we conclude *O. franksi* likely has high susceptibility to ocean acidification.

The SRR and SIR did not provide any species-specific information on the susceptibility of *O. franksi* to disease. The public comments did not provide new or supplemental information on the susceptibility of *O. franksi* to disease. Supplemental information we found on the susceptibility of *O. franksi* to disease includes the following. Disease surveys conducted between August and December 1999 at 19 reef sites from six geographic areas across the wider Caribbean (Bermuda, Puerto Rico,

Bonaire, Venezuela, Colombia, and Jamaica) revealed that *O. franksi* had the third highest incidence of disease at 1.1 to 5.6 percent across geographic locations (Weil *et al.*, 2002). Between 1998 and 2000, *O. franksi* was one of six coral species identified in the Virgin Islands as most susceptible to disease (Waddell, 2005). In 2004 in Mexico, disease prevalence was highest in *O. franksi* with 41 percent of colonies infected, followed by 34 percent of *O. annularis* colonies and 31 percent of *O. faveolata* colonies (Ward *et al.*, 2006). In Curacao colonies of *O. franksi* infected with yellow band disease lost an average of 30 percent of their tissue between 1997 and 2005, but some tagged colonies exhibited re-sheeting over disease lesions (Bruckner and Bruckner, 2006a).

All sources of information are used to describe *O. franksi*'s susceptibility to disease as follows. *Orbicella franksi* is often reported as among the species with the highest disease prevalence. Although there are few quantitative studies of the effects of disease on *O. franksi*, there is evidence that partial mortality can average about 25 to 30 percent and that disease can cause shifts to smaller size classes. Thus, we conclude that *O. franksi* is highly susceptible to disease.

The SIR and SRR did not provide any species-specific information on the trophic effects of fishing on *O. franksi*. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the trophic effects of fishing on *O. franksi*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. Thus, *O. franksi* likely has some susceptibility to the trophic effects of fishing given its low recruitment rates.

The SRR, SIR, and public comments did not provide information on the susceptibility of *O. franksi* to sedimentation, and we did not find any new or supplemental information. All sources of information are used to describe *O. franksi*'s susceptibility to sedimentation as follows. Genus information indicates sedimentation negatively affects primary production, growth rates, calcification, colony size, and abundance. Therefore, we conclude that *O. franksi* is highly susceptible to sedimentation.

The SRR, SIR, and public comments do not provide information on the susceptibility of *O. franksi* to nutrient enrichment. Supplemental information we found on the susceptibility of *O.*

*franksi* to nutrient enrichment includes the following. Field experiments indicate that nutrient enrichment significantly increases yellow band disease severity in *O. annularis* and *O. franksi* through increased tissue loss (Bruno *et al.*, 2003).

All sources of information are used to describe *O. franksi*'s susceptibility to nutrient enrichment as follows. Genus level information indicates *O. franksi* is likely susceptible to nutrient enrichment through reduced growth rates and lower recruitment. Additionally, nutrient enrichment has been shown to increase the severity of yellow band disease in *O. franksi*. Thus, we conclude that *O. franksi* is highly susceptible to nutrient enrichment.

The SRR and SIR do not provide species-specific information on the susceptibility of *O. franksi* to predation. Likewise, the public comments do not provide new or supplemental information on the susceptibility of *O. franksi* to predation. Supplemental information we found on the susceptibility of *O. franksi* to predation includes the following. Incidence of parrotfish grazing on the Belize barrier reef was second highest on *O. franksi*. However, in most habitats, the majority of *Orbicella* spp. showed little or no parrotfish grazing while only a few colonies were more heavily grazed, indicating low impact to the species overall (Rotjan, 2007).

All sources of information are used to describe *O. franksi*'s susceptibility to predation as follows. Genus-level information indicates *O. franksi* is affected by a number of predators, but both species-level and genus-level impacts appear to be minimal. We conclude that *O. franksi* has low susceptibility to predation.

The SRR and SIR did not provide information on the effects of sea level rise on *O. franksi*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *O. franksi*'s susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *O. franksi* has some susceptibility to sea level rise, but the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR do not provide species-specific information on the susceptibility of *O. franksi* to collection and trade, and the public comments do not provide new or supplemental information on its susceptibility to this threat. Supplemental information we found confirms the information in the

SRR and SIR that collection and trade is not a significant threat for the *Orbicella* species complex. Over the last decade, collection and trade of *O. franksi* has been primarily for scientific research rather than commercial purposes. Annual gross exports for collection and trade of *O. franksi* between 2000 and 2012 averaged 40 specimens (data available at <http://trade.cites.org>). Thus, we conclude that *O. franksi* has low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanism or conservation efforts for *O. franksi*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *O. franksi* occurs in six Atlantic ecoregions, and studies have confirmed the presence of *O. franksi* in an additional three ecoregions. These nine ecoregions encompass 26 kingdoms' and countries' EEZs, and the 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Caribbean Territories and Bermuda), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *O. franksi*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as the percentage of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *O. franksi* are reef fishing regulations and area management for protection and conservation. However, half of the reef fishing regulations are

limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *O. franksi*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the extinction risk for *O. franksi* are extremely low productivity (growth and recruitment), documented dramatic recent declines, and its restriction to the highly disturbed and degraded wider Caribbean region. All of these factors combined to yield a very high estimated extinction risk. It had a marginally lower risk estimate than the other two *O. annularis* complex species because of greater distribution in deep and mesophotic depth habitats, which are expected to experience lesser exposure to some surface-based threats.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *O. franksi*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. The species has undergone declines most likely from disease and warming-induced bleaching. There is evidence of synergistic effects of threats for this species including increased disease severity with nutrient enrichment. *Orbicella franksi* is highly susceptible to a number of threats, and cumulative effects of multiple threats have likely contributed to its decline and exacerbate vulnerability to extinction. Despite

declines, the species is still common and remains one of the most abundant species on Caribbean reefs. Its life history characteristics of large colony size and long life span have enabled it to remain relatively persistent despite slow growth and low recruitment rates, thus moderating vulnerability to extinction. However, the buffering capacity of these life history characteristics is expected to decrease as colonies shift to smaller size classes as has been observed in locations in its range. Its absolute population abundance has been estimated as at least tens of millions of colonies in both a portion of the U.S. Virgin Islands and the Dry Tortugas and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *O. franksi* is limited to an area with high, localized human impacts and predicted increasing threats. Its depth range of five to at least 50 m, possibly up to 90 m, moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower temperatures than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. *Orbicella franksi* occurs in most reef habitats, including both shallow and mesophotic reefs, which moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance, life history characteristics, and depth distribution, combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the threats are non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *O. franksi* was proposed for listing as endangered because of: High vulnerability to ocean warming (E) disease (C), and ocean acidification (E); high vulnerability to sedimentation (A and E) and nutrient over-enrichment (A

and E); decreasing trend in abundance (E); low relative recruitment rate (E); moderate overall distribution (based on narrow geographic distribution and wide depth distribution (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *O. franksi* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of the buffering capacity of this species' spatial and demographic traits, and the best available information above on *O. franksi*'s spatial structure, demography, threat susceptibilities, and management. This combination of factors indicates that *O. franksi* is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Orbicella franksi* is highly susceptible to ocean warming (ESA Factor E), disease (C), nutrients (A, E), ocean acidification (E), and sedimentation (A, E) and susceptible to trophic effects of fishing (A). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address global threats (D);

(2) *Orbicella franksi* is geographically located in the highly disturbed Caribbean where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future;

(3) *Orbicella franksi* has experienced a decline in benthic cover over the past two decades; and

(4) *Orbicella franksi*'s slow growth rate and low sexual recruitment limits its capacity for recovery from threat-induced mortality events throughout its range over the foreseeable future. Additionally, shifts to smaller size classes via fission and partial mortality of older, larger colonies, have reduced the buffering capacity of *O. franksi*'s life history strategy.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range, and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *O. franksi* spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *Orbicella franksi*'s distribution within the Caribbean increases its risk of exposure to threats as described above, its known depth distribution is between 5 and 50 m, with occurrence by the species complex as deep as 90 m, and its habitat includes various shallow and mesophotic reef environments. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species;

(2) Although *O. franksi* has declined in percent cover and colony size, there is evidence that population abundance has remained stable in some locations over a decadal time scale; and

(3) *Orbicella franksi* has a common occurrence and remains one of the most dominant corals in the Caribbean. It has an absolute abundance of at least tens of millions of colonies based on estimates from two locations. Absolute abundance is higher than estimates from these locations since it occurs in many other locations throughout its range. This absolute abundance allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section and thus does

not warrant listing as endangered at this time.

Range-wide, multitudes of conservation efforts are already broadly employed that are likely benefiting *O. franksi*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

### *Orbicella annularis*

#### Introduction

The SRR and SIR provided the following information on *O. annularis* morphology. *Orbicella annularis* colonies grow in columns that exhibit rapid and regular upward growth. In contrast to the other two *Orbicella* species, margins on the sides of columns are typically dead. Live colony surfaces usually lack ridges or bumps. The public comments did not provide new or supplemental information on *O. annularis*' morphology, and we did not find any new or supplemental information.

#### Spatial Information

The SRR and SIR provided the following information on the distribution, habitat and depth range of *O. annularis*. *Orbicella annularis* is common throughout the western Atlantic and greater Caribbean including the Flower Garden Banks but may be absent from Bermuda. Two personal communications were cited: one confirming its rarity in Bermuda, and the other stating *O. annularis* had not been seen in Bermuda. *Orbicella annularis* is reported from most reef environments in depths of 0.5 to 20 m. The *Orbicella* species complex is a common, often dominant component of Caribbean mesophotic reefs, suggesting the potential for deep refugia across a broader depth range, but *O. annularis* is generally described with a shallower distribution.

The public comments did not provide new or supplemental information on *O. annularis*' distribution, habitat, or depth range. Supplemental information we found includes the following. Veron (2014) confirmed the occurrence of *O. annularis* in nine out of his 11 ecoregions in the western Atlantic and greater Caribbean known to contain corals, but indicated one of these ecoregions (Bermuda) has published records of occurrence that need further

investigation. Locke (2013) indicated early records of *O. annularis* in Bermuda may be incorrect since this species was historically undifferentiated from *O. franksi* and *O. faveolata*. The two ecoregions in which it is not found are off the coasts of Brazil and the southeastern U.S. north of southern Florida (Veron, 2014).

#### Demographic Information

The SRR and SIR provided the following information on *O. annularis*' abundance and population trends. *Orbicella annularis* has been described as common overall. Demographic data collected in Puerto Rico over nine years straddling the 2005 bleaching event showed that population growth rates were stable in the pre-bleaching period (2001–2005) but declined one year after the bleaching event. Population growth rates declined even further two years after the bleaching event but returned to stasis the following year.

The public comments provided the following supplemental information on *O. annularis*' abundance and population trends. In the Florida Keys, abundance of *O. annularis* ranked 30 out of 47 coral species in 2005, 13 out of 43 in 2009, and 12 out of 40 in 2012. Extrapolated population estimates from stratified random samples were 5.6 million  $\pm$  2.7 million (SE) in 2005, 11.5 million  $\pm$  4.5 million (SE) in 2009, and 24.3 million  $\pm$  12.4 million (SE) in 2012. Size class distribution was somewhat variable between survey years, with a larger proportion of colonies in the smaller size classes in 2005 compared to 2009 and 2012 and a greater proportion of colonies in the largest size class (>90 cm) in 2012 compared to 2005 and 2009. Partial colony mortality was lowest less than 10 cm (as low as approximately 5 percent) up to approximately 70 percent in the larger size classes. In the Dry Tortugas, Florida, abundance of *O. annularis* ranked 41 out of 43 in 2006 and 31 out of 40 in 2008. The extrapolated population estimate was 0.5 million  $\pm$  0.3 million (SE) colonies in 2008. Differences in population estimates between years may be attributed to sampling effort rather than population trends (Miller *et al.*, 2013).

Supplemental information we found on *O. annularis*' abundance and population trends includes the following. In Utila, Honduras, *O. annularis* was present at 80 percent of sites surveyed between 1999 and 2000 and was the second most common coral species (Afzal *et al.*, 2001). In a survey of 31 sites in Dominica between 1999 and 2002, *O. annularis* was present at

20 percent of the sites at one to ten percent cover (Steiner, 2003).

Colony density varies by habitat and location, and range from less than 0.1 to greater than one colony per 10 m<sup>2</sup>. In surveys of 1,176 sites in southeast Florida, the Dry Tortugas, and the Florida Keys between 2005 and 2010, density of *O. annularis* ranged between 0.09 and 0.84 colonies per 10 m<sup>2</sup> and was highest on mid-channel reefs followed by inshore reefs, offshore patch reefs, and fore-reefs (Burman *et al.*, 2012). Along the east coast of Florida, density was highest in areas south of Miami (0.34 colonies per 10 m<sup>2</sup>) compared to Palm Beach and Broward Counties (0.04 colonies per 10 m<sup>2</sup>, Burman *et al.*, 2012). In surveys between 2005 to 2007 along the Florida reef tract from Martin County to the lower Florida Keys, density of *O. annularis* was approximately 1.3 colonies per 10 m<sup>2</sup> (Wagner *et al.*, 2010). Off southwest Cuba on remote reefs, *O. annularis* density was 0.31  $\pm$  0.46 (SD) per 10 m transect on 38 reef-crest sites and 1.58  $\pm$  1.29 colonies per 10 m transect on 30 reef-front sites. Colonies with partial mortality were far more frequent than those with no partial mortality which only occurred in the size class less than 100 cm (Alcolado *et al.*, 2010).

Population trends are available from a number of studies. In a study of sites inside and outside a marine protected area in Belize, *O. annularis* cover declined significantly over a ten year period (1998/99 to 2008/09) (Huntington *et al.*, 2011). In a study of ten sites inside and outside of a marine reserve in the Exuma Cays, Bahamas, cover of *O. annularis* increased between 2004 and 2007 inside the protected area and decreased outside the protected area (Mumby and Harborne, 2010). Between 1996 and 2006, *O. annularis* declined in cover by 37 percent in permanent monitoring stations in the Florida Keys (Waddell and Clarke, 2008), and, cover of *O. annularis* in permanent monitoring stations between 1996 and 1998 on a reef in the upper Florida Keys declined 71 percent (Porter *et al.*, 2001).

*Orbicella annularis* is the third most abundant coral by percent cover in permanent monitoring stations in the U.S. Virgin Islands. A decline of 60 percent was observed between 2001 and 2012 primarily due to bleaching in 2005. However, most of the mortality was partial mortality, and colony density in monitoring stations did not change (Smith, 2013).

At nine sites off Mona and Desecheo Islands, Puerto Rico, no species extirpations were noted at any site over

10 years of monitoring between 1995 and 2008. However, *O. faveolata* and *O. annularis* sustained the largest losses with the number of colonies of *O. annularis* decreasing by 19 and 20 percent at Mona and Desecheo Islands, respectively. In 1998, eight percent of all corals at six sites surveyed off Mona Island were *O. annularis* colonies, dipping to approximately 6 percent in 2008. At Desecheo Island, 14 percent of all coral colonies were *O. annularis* in 2000 and 13 percent in 2008 (Bruckner and Hill, 2009).

Surveys of a degraded and a less degraded site in a marine protected area in Cartagena, Colombia, revealed that while large, old colonies of *O. annularis* were present, colonies had experienced high partial mortality that caused high fission rates and a dominance of small, non-reproductive ramets. Ramets that were non-reproductive or less fertile (less than 46 cm<sup>2</sup>) accounted for 72 percent and 55 percent of the population at the surveyed sites, and only one percent and six percent of the ramets at the sites were large enough (200 cm<sup>2</sup>) to be fully reproductive. In addition to the small ramet size, the lack of sexual recruitment led the authors to conclude that both populations were in decline, especially at the more degraded reef where mortality was higher and ramets were smaller, as individual colonies seemed to be growing old without being replaced (Alvarado-Chacon and Acosta, 2009).

In a survey of 185 sites in five countries (Bahamas, Bonaire, Cayman Islands, Puerto Rico, and St. Kitts and Nevis) in 2010 to 2011, size of *O. annularis* and *O. franksi* colonies was significantly less than *O. faveolata*. Total mean partial mortality of *O. annularis* colonies at all sites was 40 percent. Overall, the total area occupied by live *O. annularis* declined by a mean of 51 percent, and mean colony size declined from 1927 cm<sup>2</sup> to 939 cm<sup>2</sup>. There was a 211 percent increase in small tissue remnants less than 500 cm<sup>2</sup>, while the proportion of completely live large (1,500–30,000 cm<sup>2</sup>) colonies declined. *Orbicella annularis* colonies in Puerto Rico were much larger with large amounts of dead sections. In contrast, colonies in Bonaire were also large with greater amounts of live tissue. The presence of dead sections was attributed primarily to outbreaks of white plague and yellow band disease, which emerged as corals began recovering from mass bleaching events. This was followed by increased predation and removal of live tissue by damselfish algal lawns (Bruckner, 2012a).

Hughes and Tanner (2000) documented the demographics of *O. annularis* in Jamaica from 1977 to 1993. At the beginning of the study, 86 colonies were present within monitored stations. The number of colonies increased 40 to 42 percent between 1986 and 1987 due to fission (occurring at the same time as a decline in cover) and subsequently declined steadily to 40 colonies by 1993. Rates of survival, population growth, and recruitment declined over time, and the size structure became increasingly dominated by smaller size classes (Hughes and Tanner, 2000). Mortality increased sharply between 1990 and 1993 due to the presence of smaller, more vulnerable colonies formed by partial mortality of larger colonies (Hughes, 1996). The persistence of large colonies had the greatest effect on population growth, and simulations indicated that the levels of recruitment needed to maintain population levels at 1977 levels increased sharply over time (Hughes and Tanner, 2000). Simulations with no sexual recruitment indicated that the population dynamics in the most recent period (1987 to 1993) forecasted a population of zero within approximately 25 years. Simulation using the population dynamics observed between 1982 to 1987 would result in a slower decline while the dynamics observed between 1977 and 1982 would result in population growth (Hughes and Tanner, 2000).

Cover of *O. annularis* at Yawzi Point, St. John, U.S. Virgin Islands declined from 41 percent in 1988 to approximately 12 percent by 2003 with a rapid decline beginning with the aftermath of Hurricane Hugo in 1989 and continuing between 1994 and 1999 during a time of two hurricanes (1995) and a year of unusually high sea temperature (1998), and remaining statistically unchanged between 1999 and 2003. Colony abundances declined from 47 to 20 colonies per m<sup>2</sup> between 1988 and 2003, due mostly to the death and fission of medium to large colonies ( $\geq 151$  cm<sup>2</sup>). Meanwhile, the population size class structure shifted between 1988 and 2003 to a higher proportion of smaller colonies in 2003 (60 percent less than 50 cm<sup>2</sup> in 1988 versus 70 percent in 2003) and lower proportion of large colonies (6 percent greater than 250 cm<sup>2</sup> in 1988 versus 3 percent in 2003). The changes in population size structure indicated a population decline coincident with the period of apparent stable coral cover. Population modeling forecasts the 1988 size structure would not be reestablished by recruitment and a strong likelihood of extirpation of *O.*

*annularis* at this site within 50 years (Edmunds and Elahi, 2007).

*Orbicella annularis* colonies were monitored between 2001 and 2009 at Culebra Island, Puerto Rico. The population was in demographic equilibrium (high rates of survival and stasis) before the 2005 bleaching event but suffered a significant decline in growth rate (mortality and shrinkage) for two consecutive years after the bleaching event. Partial tissue mortality due to bleaching caused dramatic colony fragmentation that resulted in a population made up almost entirely of small colonies by 2007 (97 percent were less than 50 cm<sup>2</sup>). Three years after the bleaching event, the population stabilized at a number of colonies reduced by about half, with fewer medium to large size colonies and more smaller colonies (Hernández-Pacheco *et al.*, 2011).

All information on *O. annularis*' abundance and population trends can be summarized as follows. Historically, *O. annularis* was considered to be one of the most abundant species in the Caribbean (Weil and Knowlton, 1994). Percent cover has declined between 37 to 90 percent over the past several decades at reefs at Jamaica, Belize, Florida Keys, Bahamas, Bonaire, Cayman Islands, Curacao, Puerto Rico, U.S. Virgin Islands, and St. Kitts and Nevis. Based on population estimates, there are at least tens of millions of *O. annularis* colonies present in the Florida Keys and Dry Tortugas combined. Absolute abundance is higher than the estimate from these two locations given the presence of this species in many other locations throughout its range. *Orbicella annularis* remains common in occurrence. Abundance has decreased in some areas between 19 to 57 percent, and shifts to smaller size classes have occurred in locations such as Jamaica, Colombia, Bahamas, Bonaire, Cayman Islands, Puerto Rico, U.S. Virgin Islands, and St. Kitts and Nevis. At some reefs, a large proportion of the population is comprised of non-fertile or less-reproductive size classes. Several population projections indicate population decline in the future is likely at specific sites, and local extirpation is possible within 25 to 50 years at conditions of high mortality, low recruitment, and slow growth rates. We conclude that while substantial population decline has occurred in *O. annularis*, it is still common throughout the Caribbean and remains one of the dominant species numbering at least in the tens of millions of colonies. Additionally, as discussed in the genus section, we conclude that the buffering

capacity of *O. annularis*' life history strategy that has allowed it to remain abundant has been reduced by the recent population declines and amounts of partial mortality, particularly in large colonies.

#### Other Biological Information

The SRR and SIR provided the following information on *O. annularis*' life history. *Orbicella annularis* is reported to have slightly smaller egg size and potentially smaller size/age at first reproduction than the other two species of the *Orbicella* genus.

The public comments did not provide new or supplemental information on the life history of *O. annularis*. Supplemental information we found on *O. annularis*' life history includes the following. The reported growth rate of *O. annularis* is 0.4 to 1.2 cm per year (Cruz-Piñón *et al.*, 2003; Tomascik, 1990). Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Orbicella annularis* was classified as a "stress-tolerant" species, thus likely less vulnerable to environmental stress.

The SRR and SIR provided the following other biological information for *O. annularis*. Eight percent of *O. annularis* genotypes across three sites in Belize were clones. Low tissue biomass can render specific colonies of *O. annularis* susceptible to mortality from stress events, such as bleaching or disease. This suggests that differential mortality among individuals, species, and reefs from stress events such as bleaching or disease may be at least partially a function of differential colony biomass (indicating overall coral health) as opposed to genetic or physiologic differences among corals or their symbionts.

In a 2010 cold-water event that affected south Florida, mortality of *O. annularis* was higher than any other coral species in surveys from Martin County to the lower Florida Keys. Average partial mortality was 56 percent during the cold-water event compared to 0.3 percent from 2005 to 2009. Surveys at a Florida Keys inshore patch reef, which experienced temperatures less than 18 degrees C for 11 days, revealed *O. annularis* was one of the most susceptible coral species with all colonies experiencing total colony mortality.

The public comments did not provide new or supplemental biological information on *O. annularis*.

Supplemental biological information we found includes the following. Of 117 colonies of *O. annularis* observed to spawn at a reef site off Bocas del Toro, Panama, there were 21 distinct genotypes, meaning that 82 percent of the colonies were clones (Levitan *et al.*, 2011). Individuals within a genotype spawned more synchronously than individuals of different genotypes. Colonies nearby spawned more synchronously regardless of genotype, out to about 5 m. When colonies were farther away, spawning was random.

Of 137 *O. annularis* colonies sampled in Honduras, 118 were distinct genotypes, meaning that 14 percent of the colonies were clones. Over 90 percent of genotypes were represented by a single colony, and 8 percent of the genotypes were represented by two or three colonies. One genotype had 14 colonies. Distance between clones ranged between 0.15 m to 6.94 m (Foster *et al.*, 2007).

Genetic sampling of 698 *O. annularis* colonies from 18 reefs within five countries in the Caribbean (Belize, Bahamas, Columbia, Curacao, and Honduras) revealed 466 distinct genotypes (approximately 33 percent clones). Genotypic diversity varied across the species' range from genetically diverse populations in Colombia, where every colony was unique, to genetically depauperate populations in Belize and Curacao, where a few genetic clones dominated. The contribution of clones to the local abundance of *O. annularis* increased in areas with greater hurricane frequency. Sites with higher genotypic diversity were dominated by larger colonies, and sites that experienced more frequent hurricanes were composed of smaller colonies than sites with less frequent hurricanes (Foster *et al.*, 2013).

Tissue samples of 1,424 *O. annularis* colonies at 26 reefs in 16 regions of the Caribbean (Bahamas, Cuba, Dominican Republic, Puerto Rico, British Virgin Islands, Dominica, Barbados, Tobago, Venezuela, Netherlands Antilles, Colombia, Nicaragua, Jamaica, Cayman Islands, Belize, and Honduras) produced 943 distinct genotypes (34 percent clones). Three coarse population clusters of *O. annularis* were detected: eastern (Lesser Antilles, Venezuela, and Netherlands Antilles), western (Bahamas, Cuba, Belize, and Cayman Islands), and central (Jamaica, Honduras, Nicaragua, Colombia, Puerto Rico, British Virgin Islands, and Dominican Republic). No barrier to gene flow based on absolute geographic distance was apparent (Foster *et al.*, 2012).

In a study of symbiont composition of repeatedly sampled colonies of six species in the Bahamas and the Florida Keys in 1998 and 2000 to 2004, major changes in symbiont dominance with time were observed in *O. annularis* and *O. franksi* at certain reefs in the Florida Keys. Some colonies of *O. annularis* and *O. franksi* exhibited shifts in their associations attributed to recovery from the stresses of the 1997–1998 bleaching event. Most transitions in symbiont identity ended in 2002, three to five years after the 1997–98 bleaching event (Thornhill *et al.*, 2006).

All other biological information can be summarized as follows. Asexual fission and partial mortality can lead to multiple ramets. The percentage of unique genotypes is variable by location and is reported to range between 18 and 86 percent (14 to 82 percent are clones). Colonies in areas with higher disturbance from hurricanes tend to have more clonality. Genetic data indicate that there is some population structure in the eastern, central, and western Caribbean with population connectivity within areas but not across. Although *O. annularis* is still abundant, it may exhibit high clonality in some locations.

#### Susceptibility to Threats

The threat susceptibility information from the SRR and SIR was interpreted in the proposed rule for *O. annularis*' vulnerabilities to threats as follows: High vulnerability to ocean warming, disease, acidification, sedimentation, and nutrient enrichment; moderate vulnerability to the trophic effects of fishing; and low vulnerability to sea level rise, predation, and collection and trade.

The SRR and SIR provided the following information on the susceptibility of *O. annularis* to ocean warming. Simulation models using demographic data collected in Puerto Rico over nine years straddling the 2005 bleaching forecasted extinction of the population within 100 years at a bleaching frequency of once every five to ten years.

The public comments did not provide new or supplemental information on the susceptibility of *O. annularis* to ocean warming. Supplemental information we found on the susceptibility of *O. annularis* to ocean warming includes the following. Surveys from 19 locations throughout the Caribbean indicated the bleaching event of 1995–96 was most extensive in the central and western Caribbean but only slight in the Lesser Antilles and Bermuda. Mortality of *O. annularis* from bleaching ranged from 2 to 30 percent at eight locations six

months after the onset of bleaching (Alcolado *et al.*, 2001).

Eight of 15 colonies of *O. annularis* monitored in Jamaica from 1994 to 1997 bleached in 1995. Bleaching affected polyp tissue depth, skeletal extension rate, reproduction, and density band formation, but the rate of recovery of each of these characteristics varied. Tissue depth recovered within 4 to 8 weeks after normal color returned, and growth rates returned to pre-bleaching levels once color and tissue depth returned. However, one year post bleaching, reproductive failure occurred in severely bleached colonies (bleached for 4 months and pale for an additional 3 months), and colonies that bleached mildly (bleached for 2 months with pale color for an additional 1 to 3 months) experienced reduced reproduction. Reproductive output of bleached colonies continued to be reduced two years after bleaching (Mendes and Woodley, 2002).

Stratified random surveys on back-reefs and fore-reefs between one and 30 m depth off Puerto Rico (Mona and Desecho Islands, La Parguera, Mayaguez, Boqueron, and Rincon) in 2005 and 2006 revealed severe bleaching in *O. annularis* with greater than 95 percent of colonies bleached (Waddell and Clarke, 2008). Surveys from 2005 to 2007 along the Florida reef tract from Martin County to the lower Florida Keys indicated that *O. annularis* had the seventh highest bleaching prevalence out of 30 species observed (Wagner *et al.*, 2010). During a 2009 bleaching event on Little Cayman, of the ten coral species that bleached, *O. annularis* had the second highest bleaching prevalence with approximately 45 percent of colonies bleached (van Hooidonk *et al.*, 2012).

Surveys at Culebra Island, Puerto Rico revealed extensive bleaching in 2005 with all of the *O. annularis* colonies in monitored transects bleached, and many of the surviving colonies remained pale in color after a year. Cover of *O. annularis* was reduced from 28 percent prior to the bleaching event in 2005 to 8 percent in 2009 (Hernández-Pacheco *et al.*, 2011).

In Barbados, the prevalence and abundance of the zooxanthellae *Symbiodinium trenchi* (D1a) increased in colonies of *O. annularis* in the weeks leading up to and during the 2005 bleaching event, and disproportionately dominated *O. annularis* colonies that did not bleach. In the 2-year period following the bleaching event, *S. trenchi* was displaced by other strains of *Symbiodinium* that were more competitive under less stressful conditions. The authors concluded that

it was unclear whether the rise and fall of *S. trenchi* was ecologically beneficial or whether its increased prevalence was an indicator of weakening coral health (LaJeunesse *et al.*, 2009).

Across the U.S. Virgin Islands, average bleaching of *O. annularis* was 66 percent, and paling was 16 percent, during the 2005 bleaching event. Disease prevalence of *O. annularis* was 5 percent after the 2005 bleaching. In the milder 2010 bleaching event, 58 percent of *O. annularis* colonies bleached, and 28 percent of the colonies paled. No *O. annularis* colonies suffered total mortality, but percent cover decreased from the 2.5 percent cover in 2005 before bleaching to about one percent in 2010. There was a reduction in the proportion of larger sized colonies and an increase in the proportion of smaller sized colonies due to fission of larger colonies. The authors concluded that the susceptibility to disease increased the impact of bleaching, making *O. annularis* less tolerant overall to ocean warming (Smith *et al.*, 2013b).

All sources of information are used to describe *O. annularis*' susceptibility to ocean warming as follows. *Orbicella annularis* is highly susceptible to bleaching with 45 to 100 percent of colonies observed to bleach. Reported mortality from bleaching ranges from two to 71 percent. Recovery after bleaching is slow with paled colonies observed for up to a year. Reproductive failure can occur a year after bleaching, and reduced reproduction has been observed two years post bleaching. There is indication that symbiont shuffling can occur prior to, during, and after bleaching events and result in bleaching resistance in individual colonies. We conclude that *O. annularis* is highly susceptible to ocean warming.

The SRR and SIR did not provide any species-specific information on the susceptibility of *O. annularis* to acidification, and the public comments did not provide new or supplemental information on its susceptibility to this threat. We did not find any new or supplemental information on the susceptibility of *O. annularis* to acidification. Although there is no species-specific information on the susceptibility of *O. annularis* to ocean acidification, genus information indicates the species complex has reduced growth and fertilization success under acidic conditions. Thus, we conclude *O. annularis* likely has high susceptibility to ocean acidification.

The SRR and SIR did not provide any species-specific information on the susceptibility of *O. annularis* to disease. The public comments did not provide

new or supplemental information on the susceptibility of *O. annularis* to disease. Supplemental information we found on the susceptibility of *O. annularis* to disease confirms the information on the *Orbicella* species complex and includes the following. Surveys at five sites along the west coast of Dominica between 2000 and 2002 revealed *O. annularis* was one of the species most susceptible to disease. Of the 12 species infected by white plague in 2000, *O. annularis* ranked third highest in disease prevalence (14.1 percent of infected colonies were *O. annularis*). It ranked second in 2001 out of 14 species (20.3 percent) and third in 2002 out of 13 species (12.7 percent). Although only one colony experienced total colony mortality, *O. annularis* had the third highest amount of tissue loss in the three years combined (11,717 cm<sup>2</sup>). Black band disease affected *O. annularis* in 2000 but not in any of the other survey years (Borger and Steiner, 2005).

In a 1998 outbreak of white plague in St. Lucia, three percent of *O. annularis* were affected, which was the lowest prevalence of disease of six species studied (Nugues, 2002). In surveys after the 2010 bleaching event and the passage of a hurricane, 93 percent of diseased colonies (111 of 119 colonies) surveyed in radial transects in Brewers Bay, U.S. Virgin Islands were *O. annularis* (Brandt *et al.*, 2013). Yellow band disease in *O. annularis* increased in prevalence between 1999 and 2004 on reefs near La Parguera and Desecheo and Mona Islands, Puerto Rico (Waddell, 2005).

Disease surveys conducted between August and December 1999 at 19 reef sites from six geographic areas across the wider Caribbean (Bermuda, Puerto Rico, Bonaire, Venezuela, Colombia, and Jamaica) revealed that *O. annularis* showed the highest incidence of disease at 5.5 to 12.6 percent across geographic locations. Yellow band disease showed higher incidences in Bonaire and Venezuela where a high proportion of recently dead ramets of *O. annularis* that most probably died from the disease were observed (Weil *et al.*, 2002).

In Curacao, colonies of *O. annularis* infected with yellow band disease lost 90 percent of their tissue between 1997 and 2005. Only the unaffected parts of colonies continued to grow, and only the smallest lesions healed. Partial mortality was higher in 2005 (average of 40 percent) than in 1998. Outbreaks of white plague occurred in 2001 and 2005 and infected *O. faveolata* and *O. annularis* with the highest frequency (Bruckner and Bruckner, 2006a).

All sources of information are used to describe *O. annularis*' susceptibility to disease as follows. Most studies report *O. annularis* as among the species with the highest disease prevalence. Disease can cause extensive loss in coral cover, high levels of partial colony mortality, and changes in the relative proportions of smaller and larger colonies, particularly when outbreaks occur after bleaching events. Thus, we conclude that *O. annularis* is highly susceptible to disease.

The SRR and SIR provided the following information on the susceptibility of *O. annularis* to the trophic effects of fishing. Interactions between *O. annularis* and four types of benthic algae (encrusting calcified red algae, fleshy brown macroalgae, upright calcareous green algae, and a mixed assemblage of turf algae) indicate that each alga exerts its own characteristic suite of effects on the coral holobiont, and that micro-scale dynamics have the potential to drive changes in reef community composition. Negative impacts spanned the range from micro-scale changes in microbial communities and oxygen drawdown to colony-scale effects such as damage to adjacent polyps and lowered fecundity of the adjacent colony. The public comments did not provide new or supplemental information on the susceptibility of *O. annularis* to the trophic effects of fishing, and we did not find any new or supplemental information.

All sources of information are used to describe *O. annularis*' susceptibility to the trophic effects of fishing as follows. Due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery, competition with algae can adversely affect coral recruitment. In addition, competition with algae can lead to micro-scale to colony-level negative impacts to *O. annularis*. Thus, we conclude that *O. annularis* has some susceptibility to the trophic effects of fishing. The available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR did not provide species-specific information on the susceptibility of *O. annularis* to sedimentation, and the public comments did not provide new or supplemental information on its susceptibility to this threat. Supplemental information we found confirms the information on the susceptibility of the *Orbicella* species complex to sedimentation and includes the following. In St. Lucia, rates of partial mortality of *O. annularis* and *O. faveolata* were higher close to river

mouths where sediments were deposited than they were farther from the river mouths, indicating sensitivity of these two species to sedimentation (Nugues and Roberts, 2003). Additionally, at five study sites in Puerto Rico, the cover of *O. annularis* decreased significantly with a high content of terrigenous sediments (Torres and Morelock, 2002).

All sources of information are used to describe *O. annularis*' susceptibility to sedimentation as follows.

Sedimentation can cause partial mortality and decreased coral cover of *O. annularis*. In addition, genus information indicates sedimentation negatively affects primary production, growth rates, calcification, colony size, and abundance. Therefore, we conclude that *O. annularis* has high susceptibility to sedimentation.

The SRR, SIR, and public comments do not provide information on the susceptibility of *O. annularis* to nutrient enrichment. Supplemental information we found on the susceptibility of *O. annularis* to nutrient enrichment includes the following. Field experiments indicate that nutrient enrichment significantly increases yellow band disease severity in *O. annularis* and *O. franksi* through increased tissue loss (Bruno *et al.*, 2003). In laboratory experiments, dissolved organic carbon caused significantly higher mortality of *O. annularis* after 30 days of exposure compared to controls while nutrients (phosphate, nitrate, and ammonia) did not (Kline *et al.*, 2006; Kuntz *et al.*, 2005). Dissolved organic carbon levels that resulted in significantly higher mortality compared to controls were 12.5 mg per L glucose, and 25 mg per L lactose, starch, galactose, and glucose, which were all levels reported for impacted reefs (Kline *et al.*, 2006; Kuntz *et al.*, 2005).

All sources of information are used to describe *O. annularis*' susceptibility to nutrient enrichment as follows. Elevated nutrients cause increased disease severity in *O. annularis*. Genus level information indicates elevated nutrients also cause reduced growth rates and lowered recruitment. Therefore, we conclude that *O. annularis* has high susceptibility to nutrients.

The SRR and SIR do not provide species-specific information on the susceptibility of *O. annularis* to predation. Likewise, the public comments do not provide information on the susceptibility of *O. annularis* to predation. Supplemental information we found on the susceptibility of *O. annularis* to predation includes the following. Predation by the

corallivorous snail *C. abbreviata* was present on 2.5 percent of *O. annularis* colonies surveyed in the Florida Keys in 2012 (Miller *et al.*, 2013). Parrotfish consume *O. annularis* and *O. faveolata* more intensively than other coral species, but tissue regeneration capabilities appear to be high enough to counterbalance loss from predation (Mumby, 2009).

All sources of information are used to describe *O. annularis*' susceptibility to predation as follows. *Orbicella annularis* is affected by a number of predators, but losses appear to be minimal. We conclude that *O. annularis* has low susceptibility to predation.

The SRR and SIR did not provide information on the effects of sea level rise on *O. annularis*. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *O. annularis*' susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *O. annularis* has some susceptibility to sea level rise, but the available information does not support a more precise description of susceptibility to this threat.

The SRR and SIR did not provide species-specific information on the susceptibility of *O. annularis* to collection and trade, and the public comments did not provide new or supplemental information on its susceptibility to this threat. Supplemental information we found confirms the information in the SRR and SIR that collection and trade is not a significant threat for the *Orbicella* species complex. Over the last decade, collection and trade of this species has been primarily for scientific research rather than commercial purposes. Annual gross exports for collection and trade of *O. annularis* between 2000 and 2012 averaged 1,178 specimens (data available at <http://trade.cites.org>). Thus, we conclude that *O. annularis* has a low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanism or conservation efforts for *O. annularis*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *O.*

*annularis* occurs in nine Atlantic ecoregions that encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Caribbean Territories and possibly Bermuda), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *O. annularis*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as the percentage of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *O. annularis* are reef fishing regulations and area management for protection and conservation. However, half of the reef fishing regulations are limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *O. annularis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the extinction risk for *O. annularis* include very low productivity (growth and recruitment), documented dramatic declines in abundance, restriction to the degraded reefs of the wider Caribbean region, and preferential occurrence in shallow habitats (yielding potentially greater exposure to surface-based threats).

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information,

described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *O. annularis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. The species has undergone major declines mostly due to warming-induced bleaching and disease. Several population projections indicate population decline in the future is likely at specific sites and that local extirpation is possible within 25 to 50 years at conditions of high mortality, low recruitment, and slow growth rates. There is evidence of synergistic effects of threats for this species including disease outbreaks following bleaching events and increased disease severity with nutrient enrichment. *Orbicella annularis* is highly susceptible to a number of threats, and cumulative effects of multiple threats have likely contributed to its decline and exacerbate vulnerability to extinction. Despite high declines, the species is still common and remains one of the most abundant species on Caribbean reefs. Its life history characteristics of large colony size and long life span have enabled it to remain relatively persistent despite slow growth and low recruitment rates, thus moderating vulnerability to extinction. However, the buffering capacity of these life history characteristics is expected to decrease as colonies shift to smaller size classes as has been observed in locations in its range. Its absolute population abundance has been estimated as at least tens of millions of colonies in the Florida Keys and Dry Tortugas combined and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *O.*

*annularis* is limited to an area with high, localized human impacts and predicted increasing threats. *Orbicella annularis* occurs in most reef habitats 0.5 to 20 m in depth which moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance and life history characteristics combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the threats are non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *O. annularis* was proposed for listing as endangered because of: High vulnerability to ocean warming (E) disease (C), and ocean acidification (E); high vulnerability to sedimentation (A and E) and nutrient over-enrichment (A and E); decreasing trend in abundance (E); low relative recruitment rate (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E); restriction to the Caribbean; and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *O. annularis* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of the buffering capacity of this species' spatial and demographic traits, and the best available information above on *O. annularis*' spatial structure, demography, threat susceptibilities, and management. The combination of these factors indicates that *O. annularis* is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Orbicella annularis* is susceptible to ocean warming (ESA Factor E), disease (C), sedimentation (A, E), nutrients (A, E), and ocean acidification (E) and susceptible to trophic effects of fishing (A). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address global threats (D);

(2) *Orbicella* is geographically located in the highly disturbed Caribbean where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future;

(3) *Orbicella annularis* has undergone declines in abundance and percent cover over the past two decades;

(4) *Orbicella annularis*' slow growth rate and low sexual recruitment limit its capacity for recovery from threat-induced mortality events throughout its range over the foreseeable future. Additionally, shifts to smaller size classes via fission and partial mortality of older, larger colonies, have reduced the buffering capacity of *O. annularis*' life history strategy; and

(5) Several population projections and simulations predict continued population declines and local extirpation at specific sites within the foreseeable future.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range, and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *O. annularis*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *Orbicella annularis*' distribution within the Caribbean increases its risk of exposure to threats as described above, its habitat includes most reef environments in water depths ranging from 0.5 to 20 m. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species;

(2) Although *O. annularis*' abundance has declined, it still has a common

occurrence and remains one of the most dominant corals in the Caribbean. Its absolute abundance is at least tens of millions of colonies based on estimates from two locations. Absolute abundance is higher than estimates from these locations since it occurs in many other locations throughout its range. This absolute abundance allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events; and

(3) Some evidence shows that symbiont shuffling can occur prior to, during, and after bleaching events and result in bleaching resistance in individual colonies. This indicates *O. annularis* may have some buffering capacity against warming-induced bleaching.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section and thus does not warrant listing as endangered at this time.

Range-wide, multitudes of conservation efforts are already broadly employed that are likely benefiting *O. annularis*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

#### *Genus Acropora (Caribbean)*

*Acropora* is the only genus considered in this rule that has species from both the Caribbean and the Indo-Pacific. Genus-level information for the Indo-Pacific species is described later under the section heading Genus *Acropora* (Indo-Pacific). Colonies in the Caribbean are all branching. There are over 300 nominal species in the genus *Acropora*, but in the Caribbean, there are only two species and one hybrid.

*Acropora cervicornis* and *A. palmata* can interbreed to form the hybrid *A. prolifera* (Brainard *et al.*, 2011). *Acropora cervicornis* shows genetic evidence of introgression or backcrossing with the hybrid *A. prolifera* while *A. palmata* does not (Brainard *et al.*, 2011). The reason may be that *A. palmata* eggs are more resistant to fertilization in comparison to *A. cervicornis* eggs, as evidenced by an order of magnitude higher sperm needed to maximize conspecific fertilization, lower rates of heterospecific fertilization, and reduced viability after four hours (Fogarty *et al.*, 2012c).

Caribbean acroporiids are easily distinguishable and heavily studied. Therefore, this final rule does not provide an exhaustive discussion of the spatial, demographic, and threat vulnerabilities at the genus level. That information is described below for each species.

#### *Acropora cervicornis*

##### Introduction

*Acropora cervicornis* is characterized by antler-like colonies with straight or slightly curved, cylindrical branches. The diameter of branches ranges from 0.25 to 5 cm (Lirman *et al.*, 2010a), and linear branch growth rates have been reported to range between 3 and 11.5 cm per year (*Acropora* Biological Review Team, 2005). The species can exist as isolated branches, individual colonies up to about 1.5 m diameter, and thickets comprised of multiple colonies that are difficult to distinguish (*Acropora* Biological Review Team, 2005).

##### Spatial Information

Information on *A. cervicornis*' distribution, habitat, and depth range that we considered in the proposed rule includes the following. *Acropora cervicornis* is distributed throughout the Caribbean, in the southwestern Gulf of Mexico, and in the western Atlantic. The fossil record indicates that during the Holocene, *A. cervicornis* was present as far north as Palm Beach County in southeast Florida (Lighty *et al.*, 1978), which is also the northern extent of its current distribution (Goldberg, 1973).

*Acropora cervicornis* naturally occurs on spur and groove, bank reef, patch reef, and transitional reef habitats, as well as on limestone ridges, terraces, and hardbottom habitats (Cairns, 1982; Davis, 1982; Gilmore and Hall, 1976; Goldberg, 1973; Jaap, 1984; Miller *et al.*, 2008; Wheaton and Jaap, 1988). It commonly grows in water ranging from five to 20 m in depth and has rarely been found to 60 m (Davis, 1982; Jaap,

1984; Jaap *et al.*, 1989; Schuhmacher and Zibrowius, 1985; Wheaton and Jaap, 1988). At the northern extent of its range, it grows in deeper water (16 to 30 m; Goldberg, 1973). Historically, staghorn coral was one of the primary constructors of mid-depth (10 to 15 m) reef terraces in the western Caribbean, including Jamaica, the Cayman Islands, Belize, and some reefs along the eastern Yucatan peninsula (Adey, 1978). In the Florida Keys, *A. cervicornis* occurs in various habitats but is most prevalent on patch reefs as opposed to their former abundance in deeper fore-reef habitats (Miller *et al.*, 2008). There is no evidence of range constriction, though loss of *A. cervicornis* at the reef level has occurred (*Acropora* Biological Review Team, 2005).

The public comments did not provide new or supplemental information on *A. cervicornis*' habitat or depth range. The public comments provided the following supplemental information on the distribution of *A. cervicornis*. Precht and Aronson (2004) postulate that coincident with climate warming, *A. cervicornis* only recently re-occupied its historic range after contracting to south of Miami, Florida during the late Holocene. They based this idea on the presence of large thickets off Ft. Lauderdale, Florida which were discovered in 1998 and had not been reported in the 1970s or 1980s (Precht and Aronson, 2004). However, because the presence of *A. cervicornis* in Palm Beach County, north of Ft. Lauderdale, was reported in the early 1970s (though no thicket formation was reported; Goldberg, 1973), there is uncertainty associated with whether these thickets were present prior to their discovery or if they recently appeared coincident with warming.

We did not find any new or supplemental information on habitat or depth range. Supplemental information we found on *A. cervicornis*' distribution is consistent with information considered in the proposed rule and includes the following. Veron (2014) confirms the presence of *A. cervicornis* in seven out of a potential 11 ecoregions in the western Atlantic and greater Caribbean that are known to contain corals. The four ecoregions in which it is not found are the Flower Garden Banks and off the coasts of Bermuda, Brazil, and the southeast U.S. north of south Florida. The proportion of reefs with *A. cervicornis* present decreased dramatically after the Caribbean-wide mass mortality in the 1970s and 1980s, indicating the spatial structure of the species has been affected by extirpation from many localized areas throughout its range (Jackson *et al.*, 2014).

## Demographic Information

Information on *A. cervicornis*' abundance and population trends that we considered in the proposed rule includes the following. *Acropora cervicornis* has been described as sometimes common (Veron, 2000) and uncommon (Carpenter *et al.*, 2008). *Acropora cervicornis* historically was one of the dominant species on most Caribbean reefs, forming large, monotypic thickets and giving rise to the nominal distinct zone in classical descriptions of Caribbean reef morphology (Goreau, 1959). Massive, Caribbean-wide mortality, apparently primarily from white band disease (Aronson and Precht, 2001), spread throughout the Caribbean in the mid-1970s to mid-1980s and precipitated widespread and radical changes in reef community structure (Brainard *et al.*, 2011). In addition, continuing coral mortality from periodic acute events such as hurricanes, disease outbreaks, and mass bleaching events has added to the decline of *A. cervicornis* (Brainard *et al.*, 2011). In locations where quantitative data are available (Florida, Jamaica, U.S. Virgin Islands, Belize), there was a reduction of approximately 92 to greater than 97 percent between the 1970s and early 2000s (*Acropora* Biological Review Team, 2005).

Fossil evidence from the Dominican Republic indicates that Holocene *A. cervicornis* was capable of thriving for thousands of years under highly variable temperature and salinity conditions and suggests that the recent decline in *A. cervicornis* is anomalous (Greer *et al.*, 2009). Additional fossil evidence from Belize indicates that the recent decline of *A. cervicornis* is without precedent during the late Holocene (Aronson and Precht, 2001). In contrast, two 500 year gaps in the fossil record, around 3 and 4.5 thousand years ago where dated *A. cervicornis* fragments were not observed in samples from the Florida Keys, suggests that the recent decline may not be without precedent (Shinn *et al.*, 2003). However, this study was based on radiocarbon dating of *A. cervicornis* fragments, for which the time of transport and deposition are not known, so there is uncertainty of whether these gaps represent the absence of *A. cervicornis* or variable storm depositional history (Shinn *et al.*, 2003).

Since the 2006 listing of *A. cervicornis* as threatened, continued population declines have occurred in some locations with certain populations of both species decreasing up to an additional 50 percent or more (Colella *et al.*, 2012; Lundgren and Hillis-Starr,

2008; Muller *et al.*, 2008; Rogers and Muller, 2012; Williams *et al.*, 2008).

Public comments provided the following supplemental information on *A. cervicornis*' abundance and population trends. There are some small pockets of remnant robust populations such as in southeast Florida (Vargas-Angel *et al.*, 2003), Honduras (Keck *et al.*, 2005; Riegl *et al.*, 2009), and Dominican Republic (Lirman *et al.*, 2010a). Additionally, Lidz and Zawada (2013) observed 400 colonies of *A. cervicornis* along 70.2 km of transects near Pulaski Shoal in the Dry Tortugas where the species had not been seen since the cold water die-off of the 1970s. Cover of *A. cervicornis* increased on a Jamaican reef from 0.6 percent in 1995 to 10.5 percent in 2004 (Idjadi *et al.*, 2006).

Riegl *et al.* (2009) monitored *A. cervicornis* in photo plots on the fringing reef near Roatan, Honduras from 1996 to 2005. *Acropora cervicornis* cover was 0.42 percent in 1996, declined to 0.14 percent in 1999 after the Caribbean bleaching event in 1998 and mortality from run-off associated with a Category 5 hurricane, and decreased further to 0.09 percent in 2005. *Acropora cervicornis* colony frequency decreased 71 percent between 1997 and 1999. In sharp contrast, offshore banks near Roatan had dense thickets of *A. cervicornis* with 31 percent cover in photo-quadrats in 2005 and appeared to survive the 1998 bleaching event and hurricane, most likely due to bathymetric separation from land and greater flushing. Modeling showed that under undisturbed conditions, retention of the dense *A. cervicornis* stands on the banks off Roatan is likely with a possible increased shift towards dominance by other coral species. However, the authors note that because their data and the literature seem to point to extrinsic factors as driving the decline of *A. cervicornis*, it is unclear what the future may hold for this dense population (Riegl *et al.*, 2009).

Miller *et al.* (2013) extrapolated population abundance of *A. cervicornis* in the Florida Keys and Dry Tortugas from stratified random samples across habitat types. Population estimates of *A. cervicornis* in the Florida Keys were  $10.2 \pm 4.6$  (SE) million colonies in 2005,  $6.9 \pm 2.4$  (SE) million colonies in 2007, and  $10.0 \pm 3.1$  (SE) million colonies in 2012. In the Dry Tortugas population estimates were  $0.4 \pm 0.4$  (SE) million colonies in 2006 and  $3.5 \pm 2.9$  (SE) million colonies in 2008, though the authors note their sampling scheme in the Dry Tortugas was not optimized for *A. cervicornis*. Because these population

estimates were based on random sampling, differences in abundance estimates between years may be more likely a function of sampling effort rather than population trends. In both the Florida Keys and Dry Tortugas, most of the population was dominated by small colonies less than 30 cm diameter. In the Florida Keys, partial mortality was highest in 2005, with up to 80 percent mortality observed, and lowest in 2007 with a maximum of 30 percent. In 2012, partial mortality ranged from 20 to 50 percent across most size classes.

Supplemental information we found on *A. cervicornis*' abundance and population trends includes the following. *Acropora cervicornis* was observed in 21 out of 301 stations between 2011 and 2013 in stratified random surveys designed to detect *Acropora* colonies along the south, southeast, southwest, and west coasts of Puerto Rico, and it was observed at an additional 16 sites outside of the surveyed area (García Sais *et al.*, 2013). The largest colony was 60 cm, and density ranged from 1 to 10 colonies per 15 m<sup>2</sup> (García Sais *et al.*, 2013).

While cover of *A. cervicornis* increased from 0.6 percent in 1995 to 10.5 percent in 2004 (Idjadi *et al.*, 2006) and 44 percent in 2005 on a Jamaican reef, it collapsed after the 2005 bleaching event and subsequent disease to less than 0.5 percent in 2006 (Quinn and Kojis 2008). A cold water die-off in the Florida Keys in January 2010 resulted in the complete mortality of all *A. cervicornis* colonies at 45 of the 74 reefs surveyed (61 percent), spanning the lower to upper Florida Keys (Schopmeyer *et al.*, 2012). Walker *et al.* (2012) report increasing size of two thickets (expansion of up to 7.5 times the original size of one of the thickets) monitored off southeast Florida and also noted that cover within monitored plots concurrently decreased by about 50 percent, highlighting the dynamic nature of *A. cervicornis* distribution via fragmentation and re-attachment.

New information we found on population trends includes the following. A report on the status and trends of Caribbean corals over the last century indicates that cover of *A. cervicornis* has remained relatively stable (though much reduced) throughout the region since the large mortality events of the 1970s and 1980s. The frequency of reefs at which *A. cervicornis* was described as the dominant coral has remained stable. The number of reefs with *A. cervicornis* present declined during the 1980s (from approximately 50 to 30 percent of reefs), remained relatively stable through the

1990s, and decreased to approximately 20 percent of the reefs 2000–2004, and approximately 10 percent 2005–2011 (Jackson *et al.*, 2014).

We summarize all sources of information on *A. cervicornis*' abundance and population trends as follows. Based on population estimates, there are at least tens of millions of colonies present in the Florida Keys and Dry Tortugas combined. Absolute abundance is higher than the estimate from these two locations given the presence of this species in many other locations throughout its range. The effective population size is smaller than indicated by abundance estimates due to the tendency for asexual reproduction. There is no evidence of range constriction or extirpation at the island level. However the species is absent at the reef level. Populations appear to consist mostly of isolated colonies or small groups of colonies compared to the vast thickets once prominent throughout its range, with thickets still a prominent feature at only a handful of known locations. Across the Caribbean, percent cover appears to have remained relatively stable since the population crash in the 1980s. Frequency of occurrence has decreased since the 1980s. There are examples of increasing trends in some locations (Dry Tortugas and southeast Florida), but not over larger spatial scales or longer time frames. Population model projections from Honduras at one of the only known-remaining thickets indicate the retention of this dense stand under undisturbed conditions. If refuge populations are able to persist, it is unclear whether they would be able to repopulate nearby reefs as observed sexual recruitment is low. Thus, we conclude that the species has undergone substantial population decline and decreases in the extent of occurrence throughout its range. Percent benthic cover and proportion of reefs where *A. cervicornis* is dominant have remained stable since the mid-1980s and since the listing of the species as threatened in 2006. We also conclude that population abundance is at least tens of millions of colonies, but likely to decrease in the future with increasing threats.

#### Other Biological Information

Information on *A. cervicornis*' life history that we considered in the proposed rule includes the following. *Acropora cervicornis* is a hermaphroditic broadcast spawning species. The spawning season occurs several nights after the full moon in July, August, or September, but may be split over the course of more than one lunar cycle (Szmant, 1986; Vargas-Angel

*et al.*, 2006). The estimated size at sexual maturity is 17 cm branch length, and large colonies produce proportionally more gametes than small colonies (Soong and Lang, 1992). Basal and branch tip tissue is not fertile (Soong and Lang, 1992). Sexual recruitment rates are low, and this species is generally not observed in coral settlement studies. However, laboratory studies have found that certain species of crustose-coraline algae facilitate larval settlement and post-settlement survival (Ritson-Williams *et al.*, 2010).

Reproduction occurs primarily through asexual fragmentation that produces multiple colonies that are genetically identical (Tunncliffe, 1981). The combination of branching morphology, asexual fragmentation, and fast growth rates can lead to persistence of large areas dominated by *A. cervicornis*.

The public comments did not provide new or supplemental information on *A. cervicornis*' life history. Supplemental information we found on life history includes the following. Darling *et al.* (2012) performed a biological trait-based analysis to categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Acropora cervicornis* was classified as a "competitive" species, thus likely more vulnerable to environmental stress.

All information on *A. cervicornis*' life history can be summarized as follows. The combination of rapid skeletal growth rates and frequent asexual reproduction by fragmentation can enable effective competition and can facilitate potential recovery from disturbances when environmental conditions permit. However, low sexual reproduction can lead to reduced genetic diversity and limits the capacity to repopulate sites.

Other biological information on *A. cervicornis* that we considered in the proposed rule includes the following. Vollmer and Palumbi (2007) examined 22 populations of *A. cervicornis* from nine regions in the Caribbean (Panama, Belize, Mexico, Florida, Bahamas, Turks and Caicos, Jamaica, Puerto Rico, and Curaçao) and concluded that populations greater than 500 km apart are genetically differentiated with low gene flow across the greater Caribbean. Fine-scale genetic differences have been detected at reefs separated by as little as 2 km, suggesting that gene flow in *A. cervicornis* may not occur at much smaller spatial scales (Garcia Reyes and Schizas, 2010; Vollmer and Palumbi,

2007). This fine-scale population structure was greater when considering genes of *A. palmata* introgressed in *A. cervicornis* due to back-crossing of the hybrid *A. prolifera* with *A. cervicornis* (Garcia Reyes and Schizas, 2010; Vollmer and Palumbi, 2007).

Populations in Florida and Honduras are genetically distinct from each other and other populations in the U.S. Virgin Islands, Puerto Rico, Bahamas, and Navassa (Baums *et al.*, 2010), indicating little to no larval connectivity. However, some potential connectivity between the U.S. Virgin Islands and Puerto Rico was detected and also between Navassa and the Bahamas (Baums *et al.*, 2010).

Florida populations of *A. cervicornis* have high levels of both genetic diversity and connectivity, with evidence suggesting the western Caribbean has historically been the source of genetic variation for Florida (Hemond and Vollmer, 2010). Colonies of *A. cervicornis* in Florida mostly harbored zooxanthellae Clade A, but colonies from inshore and mid-channel reefs, which experience higher sedimentation and temperature fluctuations than reefs further offshore, had a higher prominence of Clades C and D, revealing the influence of habitat on zooxanthellae associations (Baums *et al.*, 2010).

The public comments did not provide new or supplemental biological information on *A. cervicornis*, and we did not find any new or supplemental biological information. All information on *A. cervicornis*' biology can be summarized as follows. Connectivity over distances of greater than 500 km is limited, and there is evidence of restricted gene flow over much smaller spatial scales. Genetic diversity appears to be relatively high in some areas like the Florida Keys.

#### Susceptibility to Threats

Information on threat susceptibilities was interpreted in the proposed rule for *A. cervicornis*' vulnerabilities to threats as follows: High vulnerability to ocean warming, disease, acidification, sedimentation, and nutrient enrichment; moderate vulnerability to the trophic effects of fishing and predation; and low vulnerability to sea level rise and collection and trade.

Information on *A. cervicornis*' susceptibility to disease that we considered in the proposed rule includes the following. Disease is believed to be the primary cause of the region-wide decline of *A. cervicornis* beginning in the late 1970s (Aronson and Precht, 2001) and continues to have a large impact on the species. White band disease is generally associated

with the majority of disease-related mortalities, but several other diseases affect *A. cervicornis*. Ritchie and Smith (1995; 1998) described white band disease type II which is linked with a bacterial infection by *Vibrio carchariae* (Ritchie and Smith, 1998), also referred to as *V. carchariae* and *V. harveyi* (Gil-Agudelo *et al.*, 2006). Williams and Miller (2005) reported an outbreak of a transmissible disease that caused rapid tissue loss on *A. cervicornis* in the Florida Keys in 2003. The disease manifested as irregular, multifocal tissue lesions with apparently healthy tissue remaining in between, a description similar to *A. palmata* afflicted with white pox. Additionally ciliate infections have been reported by Croquer *et al.* (2006) at several locations in the Caribbean.

Few studies follow the progression of disease in individual colonies over time, but there are reports of instantaneous levels of disease at various locations. The *Acropora* Biological Review Team (2005) reported that in the 1997 to 2000 AGRRA surveys, at least 6 percent of *A. cervicornis* colonies were diseased, with greater prevalence documented from the Turks and Caicos (21 percent), Cayman Islands (20 percent), U.S. Virgin Islands (13 percent), and Cuba (8 percent). No disease was recorded on *A. cervicornis* in Jamaica, Mexico, Netherlands Antilles, Panama, and Venezuela during the 1997 to 2000 AGRRA surveys (*Acropora* Biological Review Team, 2005). Between 2001 and 2002, disease was detected at all monitored thickets off Ft. Lauderdale, Florida with mortality ranging from 0.1 to 7.5 percent per site and a mean of 1.8 percent of colony surface area affected (Vargas-Angel *et al.*, 2003). Evidence of white band disease was observed on 5.3 percent of *A. cervicornis* colonies in February 2010 at Cabezos del Cayo, Dominican Republic (Lirman *et al.*, 2010a). During a disease outbreak in the Florida Keys in 2003, 72 percent of the 20 tagged *A. cervicornis* colonies were infected; 28 percent of these suffered complete mortality while many more colonies ended up as remnants of live tissue (less than 10 percent of colony alive; Williams and Miller, 2005).

The public comments provided the following supplemental information on the susceptibility of *A. cervicornis* to disease. No disease was detected in stratified random surveys in the Florida Keys in 2007 (Miller *et al.*, 2013). Vollmer and Kline (2008) found that six percent of *A. cervicornis* genotypes (three out of 49) were resistant to white band disease during *in situ* transmission assays in Bocas del Toro, Panama.

Supplemental information we found on the susceptibility of *A. cervicornis* to disease includes the following. In Honduras, diseases were present in 32 percent of colonies (n = 181) monitored annually from 1996 to 2005 (Riegl *et al.*, 2009). Between zero and 30 percent of *A. cervicornis* colonies monitored in the middle Florida Keys were affected by disease from 2011 to 2012 (Lunz, 2013). About five percent were affected by rapid tissue loss during each quarterly monitoring period (Lunz, 2013).

All information on the susceptibility of *A. cervicornis* to disease can be summarized as follows. *Acropora cervicornis* is highly susceptible to disease as evidenced by the mass-mortality event in the 1970s and 1980s. Although disease is both spatially and temporally variable, about five to six percent of *A. cervicornis* colonies appear to be affected by disease at any one time, though incidence of disease has been reported to range from zero to 32 percent and up to 72 percent during an outbreak. There is indication that some colonies may be resistant to white band disease. *Acropora cervicornis* is also susceptible to several diseases including one that causes rapid tissue loss from multi-focal lesions. Because few studies track diseased colonies over time, determining the present-day colony and population level effects of disease is difficult. One study that monitored individual colonies during an outbreak found that disease can be a major cause of both partial and total colony mortality (Williams and Miller, 2005). Thus, we conclude that *A. cervicornis* is highly susceptible to disease.

Information on *A. cervicornis*' susceptibility to ocean warming that we considered in the proposed rule includes the following. *Acropora cervicornis* was one of the most heavily affected species during a 1987 to 1988 bleaching event in the Cayman Islands with 100 percent of colonies bleached on the deep reef terrace (18 to 29 m depth) and 83 percent bleached on the shallow reef terrace (Ghiold and Smith, 1990). In Puerto Rico, about 75 percent of *A. cervicornis* colonies bleached at 12 monitored sites during the 2005 Caribbean bleaching event (Waddell and Clarke, 2008). At Culebra Island, Puerto Rico approximately 90 percent of the *A. cervicornis* colonies had partial or total mortality during and after the 2005 bleaching event, and bleaching stress and mortality are believed to have resulted in the reproductive failure to subsequently spawn in 2006 (Waddell and Clarke, 2008).

Repeat sampling of colonies in the Florida Keys and Bahamas in 1998, and

seasonally between March 2000 and August 2004, showed that colonies of *A. cervicornis* were stable with their associations with *Symbiodinium* type A3 but sometimes had mixed symbiosis with *Symbiodinium* type (B1) (Thornhill *et al.*, 2006). The associations with *Symbiodinium* type (B1) were always short-lived (gone by next sampling period) and did not appear to be correlated with seasonal fluctuations or to follow the 1997 to 1998 bleaching event (Thornhill *et al.*, 2006). Most of the mixed symbiosis events were limited to a single colony except for one sampling period in August 2001 when all colonies at one of the Bahamian sites had mixed symbionts.

The public comments did not provide new or supplemental information on the susceptibility of *A. cervicornis* to ocean warming. Supplemental information we found on the susceptibility of *A. cervicornis* to ocean warming includes the following. In Roatan, Honduras, Riegl *et al.* (2009) monitored *A. cervicornis* and found none were bleached fully during the 1998 bleaching event, with the fourth highest partial bleaching frequency, and the highest mortality of 22 species monitored. During the 2005 bleaching event with 17 species observed, only *A. cervicornis* and *A. palmata* bleached 100 percent (all colonies bleached completely white) at two reefs in Jamaica with 90 percent mortality at one site and 10 percent at the other (Quinn and Kojis, 2008).

Van Woesik *et al.* (2012) developed a coral resiliency index based on biological traits and processes to evaluate extinction risk due to bleaching. Evaluations were performed at the genus level with genera separated between the Caribbean and Indo-Pacific. They reported *A. cervicornis* as highly vulnerable to extinction due to bleaching.

All information on the susceptibility of *A. cervicornis* to ocean warming can be summarized as follows. *Acropora cervicornis* is highly susceptible to bleaching in comparison to other coral species, and mortality after bleaching events is variable. Algal symbionts did not shift in *A. cervicornis* after the 1998 bleaching event, indicating the ability of this species to acclimatize to rising temperatures may not occur through this mechanism. Data from Puerto Rico and Jamaica following the 2005 Caribbean bleaching event indicate that temperature anomalies can have a large impact on total and partial mortality and reproductive output. Thus, we conclude that *A. cervicornis* is highly susceptible to ocean warming.

Information on *A. cervicornis*' susceptibility to acidification that we considered in the proposed rule includes the following. Renegar and Riegl (2005) performed laboratory experiments to examine the effect of nutrients and carbon dioxide on *A. cervicornis* growth. They found significantly reduced growth under carbon dioxide levels of 700 to 800  $\mu\text{atm}$ , predicted to occur this century, compared to controls. In addition, when elevated carbon dioxide was combined with increased nitrate and phosphate, growth rates were further reduced. The effect of combined nitrate, phosphate, and carbon dioxide appeared to be antagonistic at lower nutrient concentrations and additive at higher concentrations (compared to those nutrients paired with carbon dioxide separately). All corals in the combined nitrate, phosphate, and carbon dioxide treatment experienced total mortality, indicating the severe stress this combination induced.

The public comments did not provide new or supplemental information on the susceptibility of *A. cervicornis* to acidification. Supplemental information we found on the susceptibility of *A. cervicornis* to acidification includes the following. Enochs *et al.* (2014) examined the effects of carbon dioxide and light intensity on *A. cervicornis*. They found that carbon dioxide levels projected to occur by the end of the century from ocean acidification caused reduced calcification and skeletal density but no change in linear extension, surface area, or volume. High light intensity did not ameliorate reductions in calcification, and the authors concluded that the high light intensity necessary to reach saturation of photosynthesis and calcification in *A. cervicornis* may limit the effectiveness of this potentially protective mechanism.

All information on the susceptibility of *A. cervicornis* to acidification can be summarized as follows. *Acropora cervicornis* is susceptible to acidification through reduced growth, calcification, and skeletal density, and the effects of increased carbon dioxide combined with increased nutrients appear to be much worse than either stressor alone, and caused 100 percent mortality in some combination in one laboratory study. Therefore, we conclude that *A. cervicornis* is highly susceptible to acidification.

There is no species-specific information on the trophic effects of fishing on *A. cervicornis*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery,

recruitment habitat is limited. Thus, we conclude that *A. cervicornis* has some susceptibility to the trophic effects of fishing due to its low recruitment rates. However, the available information does not support a more precise description of susceptibility to this threat.

All information on *A. cervicornis*' susceptibility to sedimentation that we considered in the proposed rule includes the following. Exposure to drilling mud reduced calcification rates and protein concentrations in *A. cervicornis*, and exposure to equivalent concentrations of kaolin produced no drop in proteins and a lower drop in calcification rate, indicating the toxic effects of drilling mud are not due solely to increases in turbidity (Kendall *et al.*, 1983).

*Acropora cervicornis* has poor capacity to remove coarser sediments (250–2000  $\mu\text{m}$ ) and only slightly more capacity for removing finer sediments (62–250  $\mu\text{m}$ ; Hubbard and Pocock, 1972). Water movement (turbulence) and gravity are probably more important in removing sediments from this species than its capabilities of sloughing sediments in still water (Porter, 1987). In field experiments in Puerto Rico, *A. cervicornis* was less sensitive to single applications (200 mg per  $\text{cm}^2$ , 400 mg per  $\text{cm}^2$ , and 800 mg per  $\text{cm}^2$ ) of coarse sediment (mean grain size 0.5 mm) than *A. palmata* and *Orbicella annularis*, likely due to morphology that facilitated passive sediment removal, though some bleaching near the base of the colonies did occur (Rogers, 1983).

Lab experiments testing the effects of sedimentation and phosphate on *A. cervicornis* indicated that sediment-clearing rates declined with increased exposure from less than two hours to up to 24 hours after four weeks of treatment. Treatments resulted in degenerative changes to tissue, zooxanthellae, and gonad development and were more severe in sediment and sediment plus phosphate treatments in comparison to controls and phosphate alone (Hodel and Vargas-Angel, 2007).

*Acropora cervicornis* is sensitive to turbidity because it is highly reliant on sunlight for nutrition (Lewis, 1977; Porter, 1976). Rogers (1979) shaded a 20  $\text{m}^2$  area of reef as a partial simulation of conditions from turbidity and found that *A. cervicornis* was the first species to respond by bleaching. Three weeks after shading was initiated, most colonies of *A. cervicornis* were bleached. After shading was terminated at five weeks, at the sixth week, most branches were dead and covered with algae with growth tips deteriorating or grazed away, but a few branches recovered. After seven weeks, there

were more algae on the branches and further disintegration of branch tips.

Fossil material collected from Bocas del Toro, Panama indicated that *A. cervicornis* declined in lagoonal areas prior to 1960, coincident with intensive land clearing, and continued to decline offshore after 1960, with community structure more tolerant of turbid conditions (Cramer *et al.*, 2012).

The public comments did not provide new or supplemental information on *A. cervicornis*' susceptibility to sedimentation, and we did not find any new or supplemental information. All information on the susceptibility of *A. cervicornis* to sedimentation can be summarized as follows. *Acropora cervicornis* is susceptible to sedimentation through its sensitivity to turbidity, and increased run-off from land clearing has resulted in mortality of this species. In addition, laboratory studies indicate the combination of sedimentation and nutrient enrichment appears to be worse than the effects of either of these two stressors alone. Thus, we conclude that *A. cervicornis* has high susceptibility to sedimentation.

Information on *A. cervicornis*' susceptibility to nutrient enrichment that we considered in the proposed rule includes the following. Renegar and Riegl (2005) performed laboratory experiments to examine the effect of nutrients and carbon dioxide on *A. cervicornis* growth. Under the nutrient treatments alone, *A. cervicornis* experienced significantly lower growth rates under the higher nitrate and higher phosphate treatments, though not under the lower levels, and the combined nitrate and phosphate treatment produced significantly lower growth under both the low and high levels. All corals in the combined nitrate, phosphate, and carbon dioxide treatment experienced total mortality, indicating the severe stress this combination induced.

Lab experiments testing the effects of sedimentation and phosphate on *A. cervicornis* indicated that degenerative changes to tissue, zooxanthellae, and gonad development were more severe in sediment plus phosphate treatments in comparison to controls and phosphate alone (Hodel and Vargas-Angel, 2007).

The public comments did not provide new or supplemental information on the susceptibility of *A. cervicornis* to nutrient enrichment, and we did not find any new or supplemental information on its susceptibility to this threat. All information on the susceptibility of *A. cervicornis* to nutrient enrichment can be summarized as follows. Elevated nutrients can cause decreased growth in *A. cervicornis*. The

combined effects of nutrients with other stressors such as elevated carbon dioxide and sedimentation appear to be worse than the effects of nutrients alone, and can cause colony mortality in some combinations. Thus, we conclude that *A. cervicornis* is highly susceptible to nutrient enrichment.

Information on *A. cervicornis*' susceptibility to predation that we considered in the proposed rule includes the following. Known predators of *A. cervicornis* include the corallivorous snail *Coralliophila abbreviata* and the polychaete fireworm *Hermodice carunculata*. Fireworms engulf growing branch tips and devour the live tissue; removal of tissue from growing branch tips of *A. cervicornis* may negatively affect colony growth. Corallivorous snails have also been shown to transmit a disease that causes rapid tissue loss in *A. cervicornis* (Williams and Miller, 2005). Several species of fish including, threespot damselfish *Stegastes planifrons* and yellowtail damselfish *Microspathodon chrysurus*, do not directly feed on coral but remove live tissue to cultivate algal gardens.

In all thickets monitored off Ft. Lauderdale, Florida between 2001 and 2002, densities of fireworms ranged between 18 and 86 individuals per hectare, with predation scars affecting less than 0.2 percent of the *A. cervicornis* cover (Vargas-Angel *et al.*, 2003). Within the survey quadrats, fireworm scar sizes ranged from 1.0 to 8.0 cm, and densities ranged from 0 to 30 per m<sup>2</sup> (Vargas-Angel *et al.*, 2003). Evidence of fireworm predation was observed on 20.3 percent of colonies in Cabezos del Cayo, Dominican Republic in 2010 (Lirman *et al.*, 2010a). Yellowtail damselfish and three-spot damselfish were present on *A. cervicornis* colonies at a density of 0.50 and 0.96 fish per m<sup>2</sup>, respectively, in the Dry Tortugas National Park, near Garden Key, Florida in 2004 (Wilkes *et al.*, 2008).

The public comments provided the following supplemental information on the susceptibility of *A. cervicornis* to predation. In stratified random samples in the Florida Keys, damselfish algal gardens were detected on 1.9 percent of colonies in 2007 and 2.6 percent of colonies in 2012. Snail predation was detected on 1.3 percent of colonies in 2012 (Miller *et al.*, 2013).

Supplemental information we found on the susceptibility of *A. cervicornis* to predation includes the following. In Cabezos del Cayo, Dominican Republic, 30 percent of colonies occurred within established damselfish territories, and corallivorous snails were found on 11.3

percent of *A. cervicornis* colonies in 2010 (Lirman *et al.*, 2010a). In permanent monitoring plots in the middle Florida Keys between 2011 and 2012, about ten percent of fate-tracked *A. cervicornis* colonies were affected by fireworm predation, about five percent were affected by damselfish, and about five percent were affected by corallivorous snails (Lunz, 2013).

All information on the susceptibility of *A. cervicornis* to predation can be summarized as follows. Predators can have a negative impact on *A. cervicornis* through both tissue removal and the spread of disease. Predation pressure appears spatially variable. Removal of tissue from growing branch tips of *A. cervicornis* may negatively affect colony growth, but the impact is unknown as most studies do not report on the same colonies through time, inhibiting evaluation of the longer-term impact of these predators on individual colonies and populations. We conclude that *A. cervicornis* is highly susceptible to predation.

Information on *A. cervicornis*' susceptibility to collection and trade that we considered in the proposed rule includes the following. Over the last decade, collection and trade of this species has been low.

The public comments did not provide new or supplemental information on the susceptibility of *A. cervicornis* to collection and trade. Supplemental information we found includes the following. Over the last decade, collection and trade of this species has been primarily for scientific research rather than commercial purposes. Gross exports averaged approximately 2,500 pieces of coral per year between 2000 and 2012 (data available at <http://trade.cites.org>). We conclude that *A. cervicornis* has low susceptibility to collection and trade.

There is no species-specific information on the susceptibility of *A. cervicornis* to sea level rise. The SRR described sea level rise as an overall low to medium threat for all coral species. The public comments did not provide new or supplemental information on *A. cervicornis*' susceptibility to sea level rise, and we did not find any new or supplemental information. Thus, we conclude that *A. cervicornis* has some susceptibility to sea level rise, but the available information does not support a more precise description of susceptibility to this threat.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling

threats to all corals. However, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. cervicornis*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. We also incorporate here, the evaluation of threats to this species conducted in the 2005 status review. Records confirm that *A. cervicornis* occurs in seven Atlantic ecoregions that encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Caribbean Territories), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *A. cervicornis*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as the percentages of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *A. cervicornis* are fishing regulations and area management for protection and conservation. However, half of the fishing regulations are limited in scope and may not provide substantial protection for the species. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *A. cervicornis*. The 2005 status review and 2006 listing concluded that existing regulatory mechanisms are inadequate to control both global and local threats, and are contributing to the threatened status of the species, and we incorporate that analysis here.

Additionally, the public comments suggested that we did not fully consider the effects that conservation efforts have on the status of *A. cervicornis*. Therefore, conservation efforts are

described as follows. Conservation efforts have been underway for *A. cervicornis* for a number of years. Of 60 *Acropora* restoration efforts identified in 14 Caribbean countries, 88 percent used *A. cervicornis* including efforts in Belize, Colombia, Curaçao, Dominican Republic, Guadalupe, Honduras, Jamaica, Mexico, Puerto Rico, Turks and Caicos, U.S. Virgin Islands, and the Florida Keys (Young *et al.*, 2012). The most popular method is to use coral nurseries to propagate *A. cervicornis* for restoration (Johnson *et al.*, 2011; Young *et al.*, 2012). Fast growth rates, branching morphology, and asexual reproduction through fragmentation make *A. cervicornis* an ideal candidate for active propagation. The use of coral nursery techniques has been shown to be effective and only temporarily affect wild donor colonies from which fragments are taken to initially stock nurseries (Lirman *et al.*, 2010b). Survivorship is high (greater than 70 percent) in nurseries during the first year, but mortality due to storms, temperature anomalies, predation, and water quality have been reported (Young *et al.*, 2012). Survival rates are variable after transplanting, ranging between 43 and 95 percent during the first year (Hollarsmith *et al.*, 2012; Young *et al.*, 2012). Mortality rates of non-nursery raised transplanted *A. cervicornis* after five years were similar to those of reference or wild colonies (Garrison and Ward, 2008).

In conclusion, there are many conservation efforts aimed at increasing abundance and diversity of *A. cervicornis* throughout the Caribbean. These efforts are important, but not enough to ensure conservation unless combined with efforts to reduce the underlying threats and causes of mortality (Young *et al.*, 2012). Thus, while conservation efforts will likely enhance recovery and conservation of *A. cervicornis* at small spatial scales, they are unlikely to affect the overall status of the species, given the global nature of threats.

#### Vulnerability to Extinction

In 2006, *A. cervicornis* was listed as threatened, *i.e.*, likely to become in danger of extinction within the next 30 years, due to: (1) Recent drastic declines in abundance of the species that have occurred throughout its geographic range and abundances at historic lows; (2) the potential constriction of broad geographic ranges due to local extirpations resulting from a single stochastic event (*e.g.*, hurricanes, new disease outbreak); (3) limited sexual recruitment in some areas and unknown levels in most; and (4) occurrence of the

Allee effect (in which fertilization success declines greatly as adult density declines).

The species was not listed as endangered, *i.e.*, currently in danger of extinction, because: (1) It was showing limited, localized recovery; (2) range-wide, the rate of decline appeared to have stabilized and was comparatively slow as evidenced by persistence at reduced abundances for the past two decades; (3) it was buffered against major threats by the large number of colonies, large geographic range, and asexual reproduction; and (4) as shown by the geologic record, the species has persisted through climate cooling and heating fluctuation periods over millions of years, whereas other corals have gone extinct.

In 2012, *A. cervicornis* was proposed for listing as endangered because information available since the original 2006 listing as threatened suggested: (1) Population declines have continued to occur, with certain populations of both species decreasing up to an additional 50 percent or more since the time of listing; (2) there are documented instances of recruitment failure in some populations; (3) minimal levels of thermal stress (*e.g.*, 30 degrees C) have been shown to impair larval development, larval survivorship, and settlement success of *A. palmata*; (4) near-future levels of acidification have been demonstrated to impair fertilization, settlement success, and post-settlement growth rates in *A. palmata*; (5) on average 50 percent of the colonies are clones, meaning the effective number of genetic individuals is half the total population size; (6) the species' ranges are not known to have contracted, but with continued declines local extirpations are likely, resulting in a reduction of absolute range size. Furthermore, we took into account that the BRT identified restriction to the Caribbean as a spatial factor increasing extinction risk, though, among other things, exposure to high levels of human disturbance that result in pollution and breakage impacts. Also, while asexual reproduction (fragmentation) provides a source for new colonies (albeit clones) that can buffer natural demographic and environmental variability remains true, we believed that reliance on asexual reproduction is not sufficient to prevent extinction of the species. Last, the previous status review and listing determination underestimated the global climate change-associated impacts to *A. palmata* and *A. cervicornis*, based on our current knowledge of trends in emissions, likely warming scenarios, and ocean acidification. In particular, in the

previous determination, we identified ocean acidification only as a factor that "may be contributing" to the status of two species, in comparison to our current understanding that ocean acidification is one of the three highest order threats affecting extinction risk for corals.

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. cervicornis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. The species has undergone substantial population decline and decreases in the extent of occurrence throughout its range due mostly to disease. Although localized mortality events have continued to occur, percent benthic cover and proportion of reefs where *A. cervicornis* is dominant have remained stable over its range since the mid-1980s. There is evidence of synergistic effects of threats for this species including worse effects of nutrients in combination with acidification and sedimentation. *Acropora cervicornis* is highly susceptible to a number of threats, and cumulative effects of multiple threats are likely to exacerbate vulnerability to extinction. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *A. cervicornis* is limited to an area with high, localized human impacts and predicted increasing threats. *Acropora cervicornis*

commonly occurs in water ranging from 5 to 20 m in depth, though occurs in deeper depths of 16–30 m at the northern extent of its range, and has been rarely found to 60 m in depth. It occurs in spur and groove, bank reef, patch reef, and transitional reef habitats, as well as on limestone ridges, terraces, and hardbottom habitats. This habitat heterogeneity moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute population abundance has been estimated as at least tens of millions of colonies in the Florida Keys and Dry Tortugas combined and is higher and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. *Acropora cervicornis* has low sexual recruitment rates, which exacerbates vulnerability to extinction due to decreased ability to recover from mortality events when all colonies at a site are extirpated. In contrast, its fast growth rates and propensity for formation of clones through asexual fragmentation enables it to expand between rare events of sexual recruitment and increases its potential for local recovery from mortality events, thus moderating vulnerability to extinction. Its abundance and life history characteristics, combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the threats are non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. cervicornis* was proposed for listing as endangered because of: High vulnerability to ocean warming (E), ocean acidification (E) and disease (C); high vulnerability to sedimentation (A and E) and nutrient over-enrichment (A and E); uncommon abundance (E); decreasing trend in abundance (E); low relative recruitment rate (E); narrow overall distribution (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. cervicornis* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of

the buffering capacity of this species' spatial and demographic traits, and the best available information above on *A. cervicornis*' spatial structure, demography, threat susceptibilities, and management. The combination of these factors indicates that *A. cervicornis* is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora cervicornis* is highly susceptible to ocean warming (ESA Factor E), disease (C), ocean acidification (E), sedimentation (A, E), nutrients (A, E), and predation (C) and susceptible to trophic effects of fishing (A), depensatory population effects from rapid, drastic declines and low sexual recruitment (E), and anthropogenic and natural abrasion and breakage (A, E). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address both local and global threats (D);

(2) *Acropora cervicornis* is geographically located in the highly disturbed Caribbean where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Acropora cervicornis*' abundance is still a fraction of what it was before the mass mortality in the 1970s and 1980s, and its presence on reefs throughout its range has continued to decrease over the last decade.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. cervicornis*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. cervicornis*' distribution within the Caribbean increases its risk of exposure to threats as described above, its habitat includes spur and groove, bank reef, patch reef, and transitional reef habitats, as well as limestone ridges, terraces, and hardbottom habitats in water depths ranging from 5 to 60 m. This moderates

vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections;

(2) *Acropora cervicornis*' absolute abundance is at least tens of millions of colonies based on estimates from two locations. Absolute abundance is higher than estimates from these locations since *A. cervicornis* occurs in many other locations throughout its range, including a few small pockets of robust remnant populations. This absolute abundance allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section;

(3) Recent information indicates that percent cover and proportions of Caribbean sites where *A. cervicornis* is dominant have stabilized;

(4) *Acropora cervicornis* shows evidence of limited population expansion in some portions of its range under some circumstances (e.g., Dry Tortugas, southeast Florida); and

(5) *Acropora cervicornis* has fast growth rates and high capacity to produce clones through asexual fragmentation, which can aid in recovery from mortality events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time. Therefore, we withdraw our proposal to list *A. cervicornis* as endangered.

Progress has been made with *A. cervicornis*-specific conservation and restoration projects, albeit small-scale, and these projects are likely to increase in the future. Within some countries, *A. cervicornis*-specific conservation and restoration projects show promise for enhancing species recovery at very small spatial scales and for facilitating the persistence of the species in some areas in the face of continuing threats. Range-wide, a multitude of conservation efforts are already broadly employed specifically for *A. cervicornis*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., GHG emissions), we do not believe that any current conservation

efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

### *A. palmata*

#### Introduction

*Acropora palmata* colonies have frond-like branches, which appear flattened to near round, and typically radiate out from a central trunk and angle upward. Branches are up to 50 cm wide and range in thickness from 4 to 5 cm. Individual colonies can grow to at least 2 m in height and 4 m in diameter (*Acropora* Biological Review Team, 2005). Colonies of *A. palmata* can grow in nearly mono-specific, dense stands and form an interlocking framework known as thickets.

#### Spatial Information

Information on *A. palmata*'s distribution, habitat, and depth range that we considered in the proposed rule includes the following. *Acropora palmata* is distributed throughout the western Atlantic, Caribbean, and Gulf of Mexico. The northern extent of the range in the Atlantic is Broward County, Florida where it is relatively rare (only a few known colonies), but fossil *A. palmata* reef framework extends into Palm Beach County, Florida. There are two known colonies of *A. palmata*, which were discovered only recently in 2003 and 2005, at the Flower Garden Banks, located 161 km off the coast of Texas in the Gulf of Mexico (Zimmer *et al.*, 2006).

*Acropora palmata* often grows in thickets in fringing and barrier reefs (Jaap, 1984; Tomascik and Sander, 1987; Wheaton and Jaap, 1988) and formed extensive barrier-reef structures in Belize (Cairns, 1982), the greater and lesser Corn Islands, Nicaragua (Lighty *et al.*, 1982), and Roatan, Honduras, and built extensive fringing reef structures throughout much of the Caribbean (Adey, 1978). *Acropora palmata* commonly grows in turbulent water on the fore-reef, reef crest, and shallow spur-and-groove zone (Cairns, 1982; Miller *et al.*, 2008; Rogers *et al.*, 1982; Shinn, 1963) in water ranging from 1 to 5 m depth. Early studies termed the reef crest and adjacent seaward areas from the surface to five or six meters depth the "palmata zone" because of the domination by the species (Goreau, 1959; Shinn, 1963). Maximum depth of framework construction ranges from 3 to 12 m, and colonies generally do not form thickets below a depth of 5 m (Lighty *et al.*, 1982). Although *A. palmata*'s predominant habitat is reef crests and shallow fore-reefs less than

12 m depth, it also occurs in back-reef environments and in depths up to 30 m.

Extensive stands of dead colonies throughout the range occurred after mass mortalities during the 1970s and 1980s (see Demographic Information Below). There is no evidence of overall range constriction from the mass mortalities, but local extirpations are likely (Jackson *et al.*, 2014), resulting in a reduction of absolute range size.

The public comments did not provide new or supplemental information on *A. palmata*'s habitat or depth range but provided the following supplemental information on its distribution. Precht and Aronson (2004) suggested that the recent expansion of *A. palmata* to the Flower Garden Banks (Zimmer *et al.*, 2006) is possibly due to climate warming.

Supplemental information we found on *A. palmata*'s distribution is consistent with prior information. Veron (2014) confirms the occurrence of *A. palmata* in eight of a potential 11 ecoregions in the western Atlantic and wider-Caribbean that are known to contain corals. The three ecoregions in which *A. palmata* is not found are off the coasts of Bermuda, Brazil, and the southeast U.S. north of south Florida. The presence of the species in the Flower Garden Banks may represent a recent re-occupation of its historic range since fossil evidence indicates this species occupied the Flower Garden Banks during the early Holocene but disappeared in the middle Holocene due to sea level rise and possibly cooling temperatures (Precht *et al.*, 2014). Finally, the spatial structure of the species has been affected by extirpation from many localized areas throughout its range (Jackson *et al.*, 2014).

Supplemental information we found on *A. palmata*'s habitat and depth includes the following. Goreau (1959) described ten habitat zones on a Jamaican fringing reef from inshore to the deep slope, finding *A. palmata* in eight of the ten zones. *Acropora palmata* was very abundant in the reef crest zones, but also common in several other zones further inshore (the reef flat, rear, channel or lagoon, and inshore zones), and rare on the reef slope to 15 meters depth. Although *A. palmata* is currently much less common throughout its range than it was prior to the mid-1980s, it still occurs in multiple habitats and to depths of one to 30 m. For example, a 2005 study of Bonaire back-reefs found *A. palmata* at three of six sites, including within inshore and lagoon habitats, ranging from seven to 15 m depth. In 2003, aggregations of *A. palmata* were reported from patch reefs

at 10 to 20 m depth within the lagoon of Serrano Bank (Sanchez and Pizarro, 2005).

#### Demographic Information

Information on *A. palmata*'s abundance and population trends that we considered in the proposed rule includes the following. *Acropora palmata* has been described as usually common (Veron, 2000) and uncommon (Carpenter *et al.*, 2008). *Acropora palmata* was historically one of the dominant species on Caribbean reefs, forming large, monotypic thickets and giving rise to the nominal distinct zone in classical descriptions of Caribbean reef morphology (Goreau, 1959). Mass mortality, apparently from white-band disease (Aronson and Precht, 2001), spread throughout the Caribbean in the mid-1970s to mid-1980s and precipitated widespread and radical changes in reef community structure (Brainard *et al.*, 2011). This mass mortality occurred throughout the range of the species within all Caribbean countries and archipelagos, even on reefs and banks far from localized human influence (Aronson and Precht, 2001; Wilkinson, 2008). In addition, continuing coral mortality from periodic acute events such as hurricanes, disease outbreaks, and mass bleaching events added to the decline of *A. palmata* (Brainard *et al.*, 2011). In locations where historic quantitative data are available (Florida, Jamaica, U.S. Virgin Islands), there was a reduction of greater than 97 percent between the 1970s and early 2000s (*Acropora* Biological Review Team, 2005).

Since the 2006 listing of *A. palmata* as threatened, continued population declines have occurred in some locations with certain populations of *A. palmata* and *A. cervicornis* decreasing up to an additional 50 percent or more (Colella *et al.*, 2012; Lundgren and Hillis-Starr, 2008; Muller *et al.*, 2008; Rogers and Muller, 2012; Williams *et al.*, 2008). In addition, Williams *et al.* (2008) reported recruitment failure between 2004 and 2007 in the upper Florida Keys after a major hurricane season in 2005; less than five percent of the fragments produced recruited into the population.

The public comments provided the following supplemental information on *A. palmata*'s abundance and population trends. Several studies describe *A. palmata* populations that are showing some signs of recovery or are in good condition including in the Turks and Caicos Islands (Schelten *et al.*, 2006), U.S. Virgin Islands (Grober-Dunsmore *et al.*, 2006; Mayor *et al.*, 2006; Rogers and Muller, 2012), Venezuela (Zubillaga *et*

*al.*, 2008), and Belize (Macintyre and Toscano, 2007).

Extrapolated population estimates of *A. palmata* from stratified random samples across habitat types in the Florida Keys were  $0.6 \pm 0.5$  million (SE) colonies in 2005,  $1.0 \pm 0.3$  million (SE) colonies in 2007, and  $0.5 \pm 0.3$  million colonies in 2012. Because these population estimates are based on random sampling, differences between years may be a function of sampling effort rather than an indication of population trends. Relative to the abundance of other corals in the Florida Keys region, *A. palmata* was among the least abundant, ranking among corals that are naturally rare in abundance. No colonies of *A. palmata* were observed in surveys of the Dry Tortugas in 2006 and 2008. The size class distribution of the Florida Keys population included both small and large individuals ( $> 260$  cm), but after 2005 the majority of the colonies were smaller in size. These smallest corals (0 to 20 cm) had approximately zero to two percent partial mortality during all three survey years. Partial mortality across all other size classes was approximately 20 to 70 percent in 2005, 5 to 50 percent in 2007, and 15 to 90 percent in 2012 (Miller *et al.*, 2013).

Supplemental information we found on *A. palmata*'s abundance includes the following. Relatively abundant *A. palmata* communities have been documented from various locations, including Cuba (Alcolado *et al.*, 2010; González-Díaz *et al.*, 2010), Colombia (Sanchez and Pizarro, 2005), Venezuela (Martínez and Rodríguez Quintal, 2012), Navassa (Bruckner, 2012b), Jamaica (Jackson *et al.*, 2014), and the U.S. Virgin Islands (Muller *et al.*, 2014). Density estimates from sites in Cuba range from 0.14 colonies per  $m^2$  (Alcolado *et al.*, 2010) to 0.18 colonies per  $m^2$  (González-Díaz *et al.*, 2010). Maximum *A. palmata* density at ten sites in St. John, U.S. Virgin Islands was 0.18 colonies per  $m^2$  (Muller *et al.*, 2014).

Mayor *et al.* (2006) reported the abundance of *A. palmata* in Buck Island Reef National Monument, St. Croix, U.S. Virgin Islands. They surveyed 617 sites from May to June 2004 and extrapolated density observed per habitat type to total available habitat. Within an area of 795 ha, they estimated 97,232–134,371 (95% confidence limits) *A. palmata* colonies with any dimension of connected live tissue greater than one meter. Mean densities (colonies  $\geq 1$  m) were 0.019 colonies per  $m^2$  in branching coral-dominated habitats and 0.013 colonies per  $m^2$  in other hard bottom habitats.

Puerto Rico contains the greatest known extent of *A. palmata* in the U.S. Caribbean. Between 2006 and 2007, a survey of 431 random points in habitat suitable for *A. palmata* in six marine protected areas in Puerto Rico revealed a variable density of zero to 52 *A. palmata* colonies per 100  $m^2$  (0.52 colonies per  $m^2$ ), with average density of 3.3 colonies per 100  $m^2$  (0.03 colonies per  $m^2$ ). Total loss of *A. palmata* was evidenced in 13.6 percent of the random survey areas where only dead standing colonies were present (Schärer *et al.*, 2009).

In stratified random surveys along the south, southeast, southwest, and west coasts of Puerto Rico designed to locate *Acropora* colonies, *A. palmata* was observed at five out of 301 stations with sightings outside of the survey area at an additional two stations (García Sais *et al.*, 2013). *Acropora palmata* colonies were absent from survey sites along the southeast coast. Maximum density was 18 colonies per 15  $m^2$  (1.2 colonies per  $m^2$ ), and maximum colony size was 2.3 m in diameter (García Sais *et al.*, 2013).

Zubillaga *et al.* (2005) report densities of 3.2 colonies of *A. palmata* per 10  $m^2$  (0.32 colonies per  $m^2$ ) in Los Roques National Park, Venezuela. At ten sites surveyed in the national park in 2003 to 2004, density ranged from 0 to 3.4 colonies per 10  $m^2$  (0 to 0.34 colonies per  $m^2$ ) with four of the sites showing only standing dead colonies (Zubillaga *et al.*, 2008). In the six sites with live colonies, small (0.1 to 50  $cm^2$ ) and medium-sized (50 to 4,550  $cm^2$ ) colonies predominated over larger-sized (4,550 to 16,500  $cm^2$ ) colonies.

At Los Colorados reef in northwestern Cuba, a 2006 study at 12 reef crest sampling stations reported average *A. palmata* densities of 0.18 colonies per  $m^2$ , and that *A. palmata* made up 8.7 percent of the total live coral colonies at the study sites. The study also reported that the nearby Baracoa and Rincon de Guanabo reefs had similar *A. palmata* densities (González-Díaz *et al.*, 2010). The size of *A. palmata* colonies indicates some recruitment in Cuba, but not the proportions of sexual versus asexual recruits. In a 2005 study of 280 *A. palmata* colonies at four sites on the north coast of Cuba, 30.4 percent were less than 10 cm in diameter (González-Díaz *et al.*, 2008). In a 2006 study of approximately 1,100 *A. palmata* colonies at three sites on the north coast of Cuba, diameter and height size-classes were measured ( $<2$ , 3–5, 6–7, 8–10, 11–80, and  $>80$  cm). For the three sites combined, there were approximately 25 to 100 colonies in each of the four smaller size classes (Perera-Pérez *et al.*, 2012).

Supplemental information we found on *A. palmata*'s population trends includes the following. At eight of 11 sites in St. John, U.S. Virgin Islands, colonies of *A. palmata* increased in abundance, between 2001 and 2003, particularly in the smallest size class, with the number of colonies in the largest size class decreasing (Grober-Dunsmore *et al.*, 2006). Colonies of *A. palmata* monitored monthly between 2003 and 2009 in Haulover Bay on St. John, U.S. Virgin Islands suffered bleaching and mortality from disease but showed an increase in abundance and size at the end of the monitoring period (Rogers and Muller, 2012). The overall density of *A. palmata* colonies around St. John did not significantly differ between 2004 and 2010 with six out of the ten sites showing an increase in colony density. Size frequency distribution did not significantly change at seven of the 10 sites, with two sites showing an increased abundance of large-sized ( $> 51$  cm) colonies (Muller *et al.*, 2014).

In Colombia, *A. palmata* was present at four of the 32 plots (three of the six reefs) monitored annually from 1998 to 2004. Coverage of *A. palmata* ranged from 0.8 to 2.4 percent. Over the eight-year period, the species was stable at two reefs and declined at the other reef, likely in response to a hurricane in 1999 (Rodríguez-Ramírez *et al.*, 2010). MacIntyre and Toscano (2007) report the return of "numerous large colonies" of *A. palmata* on the shallow fore-reef at the southern limit of Carrie Bow Cay, Belize though no quantitative data were presented.

Colonies monitored in the upper Florida Keys showed a greater than 50 percent loss of tissue as well as a decline in the number of colonies, and a decline in the dominance by large colonies between 2004 and 2010 (Vardi *et al.*, 2012; Williams and Miller, 2012). Elasticity analysis from a population model based on data from the Florida Keys has shown that the largest individuals have the greatest contribution to the rate of change in population size (Vardi *et al.*, 2012). Between 2010 and 2013 *A. palmata* in the middle and lower Florida Keys had mixed trends. Population densities remained relatively stable at two sites and decreased at two sites by 21 and 28 percent (Lunz, 2013).

*Acropora palmata* monitored in Curaçao between 2009 and 2011 decreased in abundance, increased in colony size, with stable tissue abundance following hurricane damage (Bright *et al.*, 2013). The authors explained that the apparently conflicting trends of increasing colony

size but similar tissue abundance likely resulted from the loss of small-sized colonies that skewed the distribution to larger size classes, rather than colony growth.

Simulation models using data from matrix models of *A. palmata* colonies from specific sites in Curaçao (2006–2011), the Florida Keys (2004–2011), Jamaica (2007–2010), Navassa (2006 and 2009), Puerto Rico (2007 and 2010), and the British Virgin Islands (2006 and 2007) indicate that most of these studied populations will continue to decline in size and extent by 2100 if background environmental conditions remain unchanged (Vardi, 2011). In contrast, the studied populations in Jamaica were projected to increase in abundance, and studied populations in Navassa were projected to remain stable. Studied populations in the British Virgin Islands were predicted to decrease slightly from their initial very low levels. Studied populations in Florida, Curaçao, and Puerto Rico were predicted to decline to zero by 2100. Because the study period did not include physical damage (storms), the population simulations in Jamaica, Navassa, and the British Virgin Islands may have contributed to the differing projected trends at sites in these locations.

New information we found on population trends includes the following. A report on the status and trends of Caribbean corals over the last century indicates that cover of *A. palmata* has remained relatively stable at approximately one percent throughout the region since the large mortality events of the 1970s and 1980s. The report also indicates that the number of reefs with *A. palmata* present steadily declined from the 1980s to 2000–2004, then remained stable between 2000–2004 and 2005–2011. *Acropora palmata* was present at about 20 percent of reefs surveyed in both the 5-year period of 2000–2004 and the 7-year period of 2005–2011. *Acropora palmata* was dominant on approximately five to ten percent of hundreds of reef sites surveyed throughout the Caribbean during the four periods of 1990–1994, 1995–1999, 2000–2004, and 2005–2011 (Jackson *et al.*, 2014).

All information on *A. palmata*'s abundance and population trends is summarized as follows. Based on population estimates there are at least hundreds of thousands of *A. palmata* colonies present in both the Florida Keys and St. Croix, U.S. Virgin Islands. Absolute abundance is higher than estimates from these two locations given the presence of this species in many other locations throughout its range.

The effective population size is smaller than indicated by abundance estimates due to the tendency for asexual reproduction. Across the Caribbean, percent cover appears to have remained relatively stable since the population crash in the 1980s. Frequency of occurrence has decreased since the 1980s, indicating potential decreases in the extent of occurrence and effects on the species' range. However, the proportions of Caribbean sites where *A. palmata* is present and dominant have recently stabilized. There are locations such as the U.S. Virgin Islands where populations of *A. palmata* appear stable or possibly increasing in abundance and some such as the Florida Keys where population number appears to be decreasing. In some cases when size class distribution is not reported, there is uncertainty of whether increases in abundance indicate growing populations or fragmentation of larger size classes into more small-sized colonies. From locations where size class distribution is reported, there is evidence of recruitment, but not the proportions of sexual versus asexual recruits. The best evidence of recovery would come from multi-year studies showing an increase in the overall amount of living tissue of this species, growth of existing colonies, and an increase in the number of small corals arising from sexual recruitment (Rogers and Muller, 2012). Simulation models predict by 2100 that *A. palmata* will become absent at specific sites in several locations (Florida, Curacao, and Puerto Rico), decrease at specific sites in the British Virgin Islands, remain stable at specific sites in Navassa, and increase at specific sites in Jamaica. These simulations are based on the assumption that conditions experienced during the monitoring period, ranging from one to seven years depending on location, would remain unchanged in the future. We conclude there has been a significant decline of *A. palmata* throughout its range, with recent population stability at low percent coverage. We also conclude that absolute abundance is at least hundreds of thousands of colonies, but likely to decrease in the future with increasing threats.

#### Other Biological Information

Information on *A. palmata*'s life history that we considered in the proposed rule includes the following. Growth rates, measured as skeletal extension of the end of branches, range from 4 to 11 cm per year (*Acropora* Biological Review Team, 2005) but in Curaçao have been reported to be slower

today than they were several decades ago (Brainard *et al.*, 2011).

*Acropora palmata* is a hermaphroditic broadcast spawning species that reproduces after the full moon of July, August, and/or September (*Acropora* Biological Review Team, 2005). The estimated size at sexual maturity is 1600 cm<sup>2</sup>, and growing edges and encrusting base areas are not fertile (Soong and Lang, 1992). Larger colonies have higher fecundity per unit area, as do the upper branch surfaces (Soong and Lang, 1992). Although self-fertilization is possible, *A. palmata* is largely self-incompatible (Baums *et al.*, 2005a; Fogarty *et al.*, 2012b).

Reproduction occurs primarily through asexual fragmentation that produces multiple colonies that are genetically identical (Bak and Crieens, 1982; Highsmith, 1982; Lirman, 2000; Miller *et al.*, 2007; Wallace, 1985). Storms can be an important mechanism to produce fragments to establish new colonies (Fong and Lirman, 1995). Fragmentation is an important mode of reproduction in many reef-building corals, especially for branching species such as *A. palmata* (Highsmith, 1982; Lirman, 2000; Wallace, 1985). However, in the Florida Keys where populations have declined, there have been reports of failure of asexual recruitment due to high fragment mortality after storms (Porter *et al.*, 2012; Williams and Miller, 2010; Williams *et al.*, 2008).

Sexual recruitment rates are low, and this species is generally not observed in coral settlement studies. Laboratory studies have found that certain species of crustose-coraline algae facilitate larval settlement and post-settlement survival (Ritson-Williams *et al.*, 2010). Rates of post-settlement mortality after nine months are high based on settlement experiments (Szmant and Miller, 2005).

The public comments did not provide new or supplemental information on *A. palmata*'s life history. Supplemental information we found on *A. palmata*'s life history includes the following. Split spawning (spawning over a two month period) has been reported from the Florida Keys (Fogarty *et al.*, 2012b). Laboratory experiments have shown that some individuals (*i.e.*, genotypes) are sexually incompatible (Baums *et al.*, 2013) and that the proportion of eggs fertilized increases with higher sperm concentration (Fogarty *et al.*, 2012b). Experiments using gametes collected in Florida had lower fertilization rates than those from Belize, possibly due to genotype incompatibilities (Fogarty *et al.*, 2012b).

Darling *et al.* (2012) performed a biological trait-based analysis to

categorize coral species into four life history strategies: Generalist, weedy, competitive, and stress-tolerant. The classifications were primarily separated by colony morphology, growth rate, and reproductive mode. *Acropora palmata* was classified as a “competitive” species, thus likely more vulnerable to environmental stress.

All information on *A. palmata*'s life history can be summarized as follows. The combination of rapid skeletal growth rates and frequent asexual reproduction by fragmentation can enable effective competition within, and domination of, reef-building coral communities in high-energy environments such as reef crests. Rapid skeletal growth rates and frequent asexual reproduction by fragmentation facilitate potential recovery from disturbances when environmental conditions permit (Highsmith, 1982; Lirman, 2000). However, low sexual reproduction can lead to reduced genetic diversity and limits the capacity to repopulate sites.

Other biological information on *A. palmata* that we considered in the proposed rule includes the following. Genetic samples from 11 locations throughout the Caribbean indicate that *A. palmata* populations in the eastern Caribbean (St. Vincent and the Grenadines, U.S. Virgin Islands, Curaçao, and Bonaire) have had little or no genetic exchange with populations in the western Atlantic and western Caribbean (Bahamas, Florida, Mexico, Panama, Navassa, and Puerto Rico) (Baums *et al.*, 2005b). While Puerto Rico is more closely connected with the western Caribbean, it is an area of mixing with contributions from both regions (Baums *et al.*, 2005b). Models suggest that the Mona Passage between the Dominican Republic and Puerto Rico acts as a filter for larval dispersal and gene flow between the eastern Caribbean and western Caribbean (Baums *et al.*, 2006b).

The western Caribbean is characterized by genetically depauperate populations with lower densities ( $0.13 \pm 0.08$  colonies per  $m^2$ ), while denser ( $0.30 \pm 0.21$  colonies per  $m^2$ ), genotypically rich stands characterize the eastern Caribbean (Baums *et al.*, 2006a). Baums *et al.* (2006a) concluded that the western Caribbean had higher rates of asexual recruitment and that the eastern Caribbean had higher rates of sexual recruitment. They postulated these geographic differences in the contribution of reproductive modes to population structure may be related to habitat characteristics, possibly the amount of shelf area available.

Genotypic diversity is highly variable. At two sites in the Florida Keys, only one genotype per site was detected out of 20 colonies sampled at each site (Baums *et al.*, 2005b). In contrast, all 15 colonies sampled in Navassa had unique genotypes (Baums *et al.*, 2006a). Some sites have relatively high genotypic diversity such as in Los Roques, Venezuela (118 unique genotypes out of 120 samples; Zubillaga *et al.*, 2008) and in Bonaire and Curacao (18 genotypes of 22 samples and 19 genotypes of 20 samples, respectively; Baums *et al.*, 2006a). In the Bahamas, about one third of the sampled colonies were unique genotypes, and in Panama between 24 and 65 percent of the sampled colonies had unique genotypes, depending on the site (Baums *et al.*, 2006a).

The public comments did not provide new or supplemental biological information on *A. palmata*. Supplemental biological information we found includes the following. A genetic study found significant population structure in Puerto Rico locations (Mona Island, Desecheo Island, La Parguerain, La Parguera) both between reefs and between locations; population structure in La Parguera suggests restriction of gene flow between some reefs in close proximity (Garcia Reyes and Schizas, 2010). A more-recent study provided additional detail on the genetic structure of *A. palmata* in Puerto Rico, as compared to Curacao, the Bahamas, and Guadeloupe that found unique genotypes in 75 percent of the samples with high genetic diversity (Mège *et al.*, 2014). The recent results support two separate populations of *A. palmata* in the eastern Caribbean and western Caribbean; however, there is less evidence for separation at Mona Passage, as found by Baums *et al.* (2006b).

All biological information on *A. palmata* can be summarized as follows. Genotypic diversity is variable across the range with some populations showing evidence of higher input from sexual recruitment versus others that rely more heavily on asexual recruitment for population maintenance. There are many areas with many unique genotypes. Connectivity and mixing appear limited across larger geographic scales with eastern Caribbean populations relatively isolated from western Caribbean populations, with evidence of population structure at a local scale in some locations.

#### Susceptibility to Threats

Information on threat susceptibilities was interpreted in the proposed rule for

*A. palmata*'s vulnerability to threats as follows: High vulnerability to ocean warming, disease, acidification, sedimentation, and nutrient enrichment; moderate vulnerability to the trophic effects of fishing and predation; and low vulnerability to sea level rise and collection and trade.

Information on *A. palmata*'s susceptibility to disease that we considered in the proposed rule includes the following. Disease is believed to be the primary cause of the region-wide decline of *A. palmata* beginning in the late 1970s and continues to have a large effect on the species. White band disease was generally associated with the majority of disease-related mortalities in *A. palmata* from the 1970s to 1990s (Aronson and Precht, 2001). White pox has been described as having severe impacts on *A. palmata*, and most monitoring information after 2000 indicates that lesion patterns resembling white pox have higher prevalence than patterns resembling white band disease (Acropora Biological Review Team, 2005). In the Florida Keys, the causative agent of white pox was identified as a bacterium linked to human sewage and potential vectors/reservoirs such as corallivores (Patterson *et al.*, 2002; Sutherland *et al.*, 2011).

The effects of white pox appear to be exacerbated by higher temperatures. In Hawksnest Bay, U.S. Virgin Islands during the 2005 bleaching event, the prevalence of white pox had a positive linear relationship with temperature, with mortality increasing with bleaching, indicating a decreased resilience to disease when colonies were stressed (Muller *et al.*, 2008).

Disease is temporally and spatially variable and is often reported as an instantaneous measure of prevalence (percent of colonies affected by disease) that provides only a snapshot in time. For instance, in Puerto Rico disease affected an average of 6.7 percent of colonies from December 2006 to October 2007 (Schärer *et al.*, 2009). In St. Croix U.S. Virgin Islands, white band disease affected three percent of the colonies surveyed in Buck Island Reef National Monument between May and June 2004 (Mayor *et al.*, 2006).

Studies of permanently marked colonies, or monitoring plots, show longer-term trends of disease and mortality over time. From January 2003 to December 2009, 90 percent of the 69 monitored *A. palmata* colonies in Haulover Bay, St. John, U.S. Virgin Islands exhibited signs of disease, and the most significant cause of whole colony mortality (Rogers and Muller, 2012). Of colonies monitored in the

Florida Keys from 2004 to 2011, disease was the second highest cause of tissue mortality after physical damage from storms (33 percent of all mortality attributed to disease, Williams and Miller, 2012).

The public comments did not provide new or supplemental information on the susceptibility of *A. palmata* to disease, and we did not find any new or supplemental information. Information on the susceptibility of *A. palmata* to disease can be summarized as follows. *Acropora palmata* is highly susceptible to disease as evidenced by the mass-mortality event in the 1970s and 1980s. White pox seems to be more common today than white band disease. The effects of disease are spatially and temporally (both seasonally and inter-annually) variable. Results from longer-term monitoring studies in the U.S. Virgin Islands and the Florida Keys indicate that disease can be a major cause of both partial and total colony mortality. Thus, we conclude that *A. palmata* is highly susceptible to disease.

Information on *A. palmata*'s susceptibility to ocean warming that we considered in the proposed rule includes the following. High temperatures can cause bleaching and mortality of *A. palmata*. In St. Croix, U.S. Virgin Islands, colonies differentially bleached in Buck Island National Monument during the 2005 Caribbean-wide mass bleaching event; colonies in the shallower back reef bleached earlier and suffered greater tissue loss than those located elsewhere (Lundgren and Hillis-Starr, 2008). Data from two sites in Jamaica, found 100 percent of *A. palmata* colonies bleached at both sites in 2005, with greater than 50 percent of the colonies suffering partial mortality (Quinn and Kojis, 2008). At one site, bleached colonies had complete mortality only occasionally, and 15 percent of bleached colonies died at the second site (Quinn and Kojis, 2008). In Trunk Bay and Saltpond, St. John, U.S. Virgin Islands, almost half of the colonies that bleached in 2005 suffered partial or complete mortality (44 percent of 27 colonies and 40 percent of 107 colonies, respectively, Rogers *et al.*, 2006). Negligible bleaching of *A. palmata* was observed during a 2006 bleaching event in Navassa that affected corals at deeper depths (between 18 and 37 m) more significantly than at shallower depths (<10 m), likely due to decreased water motion at the deeper sites (Miller *et al.*, 2011a). Repeated sampling of the same colonies in the Florida Keys and Bahamas in 1998 and seasonally between March 2000 and August 2004 showed that colonies of *A. palmata* did

not change their association with *Symbiodinium* type A3 throughout the study period that included the 1997–98 bleaching event (Thornhill *et al.*, 2006).

High water temperatures also affect *A. palmata* reproduction. *Acropora palmata* embryos and larvae exhibited more developmental abnormalities, lower survivorship, and decreased settlement at 30 degrees and 31.5 degrees C compared to those at 28 degrees C (Randall and Szmant, 2009).

The public comments did not provide new or supplemental information on the susceptibility of *A. palmata* to ocean warming. Supplemental information we found includes the following. *Acropora palmata* larvae exhibited faster development and faster swimming speed at 30 and 31.5 degrees C compared to controls at 27 and 28 degrees C (Baums *et al.*, 2013). The authors suggested these changes could decrease average larval dispersal distances, and cause earlier larval settlement, thereby affecting gene flow among populations (Baums *et al.*, 2013).

A 14-year study was conducted at nine sites around Little Cayman from 1999 to 2012 of live coral cover, juvenile densities, and size structure of coral colonies to determine response to the 1998 bleaching event inside versus outside of marine protected areas. Over the first half of the study, bleaching and disease caused live cover to decrease from 26 percent to 14 percent in all corals, with full recovery seven years later with no differences inside versus outside of marine protected areas. The numbers of *A. palmata* colonies in regularly-observed size-classes did not decrease during this study, which the authors suggested may indicate resistance to bleaching and disease. The study concluded that the health of the coral assemblage and the similarity of responses inside and outside the marine protected area suggested that negligible anthropogenic disturbance at the local scale was a key factor underlying the observed resilience (Manfrino *et al.*, 2013).

Van Woesik *et al.* (2012) developed a coral resiliency index based on biological traits and processes to evaluate extinction risk due to bleaching. Evaluations were performed at the genus level, but genera were separated between the Caribbean and Indo-Pacific. They indicated that *A. palmata* is highly vulnerable to extinction.

All information on the susceptibility of *A. palmata* to ocean warming can be summarized as follows. High water temperatures affect *A. palmata* through bleaching, lowered resistance to disease, and effects on reproduction.

Temperature-induced bleaching and mortality following bleaching are temporally and spatially variable. Bleaching associated with the high temperatures in 2005 had a large impact on *A. palmata* with 40 to 50 percent of bleached colonies suffering either partial or complete mortality in several locations. Algal symbionts did not shift in *A. palmata* after the 1998 bleaching event indicating the ability to adapt to rising temperatures may not occur through this mechanism. However, *Acropora palmata* showed evidence of resistance to bleaching from warmer temperatures in some portions of its range under some circumstances (Little Cayman). Through the effects on reproduction, high temperatures can potentially decrease larval supply and settlement success, decrease average larval dispersal distances, and cause earlier larval settlement, thereby affecting gene flow among populations. Therefore, we conclude that *A. palmata* is highly susceptible to ocean warming.

Information on *A. palmata*'s susceptibility to acidification that we considered in the proposed rule includes the following. Ocean acidification has a negative impact on early life stages of *A. palmata*. Compared to controls at 400  $\mu\text{atm}$ , carbon dioxide levels of 560 and 800  $\mu\text{atm}$ , predicted to occur this century, reduced the rate of fertilization and settlement (combined 52 and 73 percent, respectively) and post-settlement growth (39 and 50 percent, respectively) of *A. palmata* in lab experiments, and impairment of fertilization was exacerbated at lower sperm concentrations (Albright *et al.*, 2010).

The public comments did not provide new or supplemental information on the susceptibility of *A. palmata* to acidification. Supplemental information we found on its susceptibility to this threat includes the following. No effects on the progression or timing of larval development, or embryo and larval size were detected at elevated carbon dioxide levels of 700  $\mu\text{atm}$  or 1000  $\mu\text{atm}$  (Medina-Rosas *et al.*, 2013).

All information on the susceptibility of *A. palmata* to acidification can be summarized as follows. Ocean acidification will likely impact fertilization, settlement success, and post-settlement growth of *A. palmata*. Therefore, we conclude that *A. palmata* is highly susceptible to acidification.

There is no species-specific information on the trophic effects of fishing on *A. palmata*. However, due to the level of reef fishing conducted in the Caribbean, coupled with *Diadema* die-off and lack of significant recovery,

recruitment habitat is limited. Therefore, the trophic effects of reef fishing adversely affects *A. palmata*'s recruitment habitat. Thus, we conclude that *A. palmata* has some susceptibility to the trophic effects of reef fishing due to low natural recruitment rates. However, the available information does not support a more precise description of susceptibility to this threat.

Information on *A. palmata*'s susceptibility to sedimentation that we considered in the proposed rule includes the following. The morphology of *A. palmata* contributes to its sensitivity to sedimentation as it is poorer at removing sediment compared to mounding corals such as *Orbicella annularis* and *Diploria strigosa* (Abdel-Salam *et al.*, 1988). Out of five species tested, *A. palmata* was the least tolerant of sediment exposure; single applications of 200 mg per cm<sup>2</sup> to colonies caused coral tissue death as sediments accumulated on the flattened, horizontal surfaces (Rogers, 1983). It is generally unable to remove coarser sediments and only weakly able to remove finer sediments (*Acropora* Biological Review Team, 2005). Water movement and gravity are probably more important in removing sediments from this species than their capabilities of sloughing sediments in stagnant water (*Acropora* Biological Review Team, 2005). Because *A. palmata* is highly dependent on sunlight for nutrition, it is also sensitive to suspended sediments that reduce water clarity (Porter, 1976).

The public comments did not provide new or supplemental information on *A. palmata*'s susceptibility to sedimentation. Supplemental information we found on the susceptibility of *A. palmata* to sedimentation includes the following. In Vega Baja, Puerto Rico, *A. palmata* mortality increased to 52 percent concurrent with pollution and sedimentation associated with raw sewage and beach nourishment, respectively, between December 2008 and June 2009 (Hernandez-Delgado *et al.*, 2011). Mortality presented as patchy necrosis-like and white pox-like conditions that impacted local reefs following anthropogenic disturbances and was higher inside the shallow platform (52 to 69 percent) and closer to the source of pollution (81 to 97 percent) compared to the outer reef (34 to 37 percent; Hernandez-Delgado *et al.*, 2011).

All information on the susceptibility of *A. palmata* to sedimentation can be summarized as follows. *Acropora palmata* is sensitive to sedimentation due to its poor capability of removing

sediment and its high reliance on clear water for nutrition, and sedimentation can cause tissue mortality. We conclude that *A. palmata* is highly susceptible to sedimentation.

Information on *A. palmata*'s susceptibility to nutrient enrichment that we considered in the proposed rule includes the following. There are few studies of the effects of nutrients on *A. palmata*. Field experiments indicate that the mean net rate of uptake of nitrate by *A. palmata* exceeds that of ammonium by a factor of two and that *A. palmata* does not uptake nitrite (Bythell, 1990).

The public comments did not provide new or supplemental information on the susceptibility of *A. palmata* to nutrient enrichment. Supplemental information we found on the susceptibility to this threat includes the following. In Vega Baja, Puerto Rico, *A. palmata* mortality increased to 52 percent concurrent with pollution and sedimentation associated with raw sewage and beach nourishment, respectively, between December 2008 and June 2009 (Hernandez-Delgado *et al.*, 2011). Mortality presented as patchy necrosis-like and white pox-like conditions that impacted local reefs following anthropogenic disturbances and was higher inside the shallow platform (52 to 69 percent) and closer to the source of pollution (81 to 97 percent) compared to the outer reef (34 to 37 percent; Hernandez-Delgado *et al.*, 2011).

All information on the susceptibility of *A. palmata* to nutrient enrichment can be summarized as follows. *Acropora palmata* is sensitive to nutrients as evidenced by increased mortality after exposure to raw sewage. We conclude that *A. palmata* is highly susceptible to nutrient enrichment.

Information on *A. palmata*'s susceptibility to predation that we considered in the proposed rule includes the following. There are several known predators of *A. palmata* including the corallivorous snail *Coralliophila abbreviata* (Baums *et al.*, 2003) and the polychaete worm *Hermodice carrunculata*. Incidental corallivores that affect *A. palmata* include several species of fish such as stoplight parrotfish *Sparisoma viride* and three-spot damselfish *Stegastes planifrons*. *Stegastes planifrons* does not directly feed on the coral but removes live tissue to cultivate algal gardens. Likewise, parrotfish are primarily herbivores and may be feeding on endolithic algae in coral tissue (Bruckner *et al.*, 2000). Monitoring in the Florida Keys indicates that parrotfish bites on *A. palmata* usually heal in a matter of weeks to months

(*Acropora* Biological Review Team, 2005). Predators have been identified as potential vectors and reservoirs of disease (Sutherland *et al.*, 2011).

The corallivorous snail *C. abbreviata* is the main predator, removing up to 16 cm<sup>2</sup> of tissue per day (Brawley and Adey 1982), and there is evidence that they concentrate on remnant *Acropora* populations following decline (*Acropora* Biological Review Team, 2005). Severity of predation is variable, and *Coralliophila* seem to be extremely rare or absent on *Acropora* spp. in certain areas such as the Dry Tortugas, Florida and Bocas del Toro, Panama (*Acropora* Biological Review Team, 2005). In St. John, U.S. Virgin Islands, snail predation affected a total of six percent of the colonies across 29 sites, but at individual sites, predation affected up to 60 percent of the colonies (Grober-Dunsmore *et al.*, 2006). In Los Roques, Venezuela snail predation was the most common cause of partial mortality (4 to 20 percent), and it affected 0.72 to 10.6 percent of the colonies (Zubillaga *et al.*, 2008). Surveys of 235 sites throughout the Florida Keys in 2007 revealed that about five percent of the *A. palmata* colonies assessed for condition were affected via predation by snails and damselfish (Miller *et al.*, 2008). In Puerto Rico, infestations of corallivorous snails were observed on three percent of all *A. palmata* colonies surveyed and ranged from 0.9 to 10.6 percent per site (Schärer *et al.*, 2009).

The public comments did not provide new or supplemental information on the susceptibility of *A. palmata* to predation. Supplemental information we found on the susceptibility of *A. palmata* to predation includes the following. Of the 50 percent tissue loss experienced during monitoring in the Florida Keys between 2004 and 2010, snail predation accounted for 15 percent after storm damage (42 percent) and disease (33 percent; Williams and Miller, 2012). The honeycomb cowfish *Acanthostracion polygonius* has been observed biting *A. palmata* and causing tissue lesions; it is unknown whether the fish is actively feeding on the coral tissue or if lesions are a by-product of its foraging mode (Williams and Bright, 2013). Lesions healed rapidly (less than six weeks) and did not contribute to significant losses of live tissue (Williams and Bright, 2013).

All information on the susceptibility of *A. palmata* to predation can be summarized as follows. Predators can have an impact on *A. palmata* both through tissue removal and the potential to spread disease. Predation pressure is spatially variable and almost non-existent in some locations. However, the

effects of predation can become more severe if colonies decrease in abundance and density, as predators focus on the remaining living colonies. Therefore, we conclude that *A. palmata* has high susceptibility to predation.

Information on *A. palmata*'s susceptibility to sea level rise that we considered in the proposed rule includes the following. In-place colonies of *A. palmata* have been used in the geologic record for reconstructing Holocene sea level because this species only develops monospecific thickets in waters less than 5 m deep and is generally limited to depths of 10 m or less (Blanchon, 2005; Blanchon *et al.*, 2009). A sustained sea level rise of more than 14 mm per year is likely to displace *A. palmata* from its thicket-forming, framework-building depth range ( $\leq 5$  m) into its remaining habitat range where a mixed framework is likely to develop (Brainard *et al.*, 2011). In the Yucatan region of Mexico during the warming that led to the last interglacial period, *A. palmata* was able to keep up with the first 3 m of rapid sea-level rise; continued sea-level rise led to the demise of the original fore-reef crests inhabited by *A. palmata*, the retreat of *A. palmata* to a more inland site, and back-stepping of the reef crest as sea level rose an additional 2 to 3 m (total of 6 m over an ecological time scale; Brainard *et al.*, 2011).

The public comments did not provide new or supplemental information on *A. palmata*'s susceptibility to sea level rise, and we did not find any new or supplemental information. All information on the susceptibility of *A. palmata* to sea level rise can be summarized as follows. The fast growth rate of *A. palmata* could accommodate deeper water. We conclude that *A. palmata* has a low susceptibility to sea level rise.

Information on *A. palmata*'s susceptibility to collection and trade that we considered in the proposed rule includes the following. Over the last decade, collection and trade of this species has been low. The public comments did not provide new or supplemental information on the susceptibility of *A. palmata* to collection and trade. Supplemental information we found includes the following. Gross exports averaged 2,120 pieces of coral per year between 2000 and 2012 and have primarily been for scientific purposes (data available at <http://trade.cites.org>). We conclude that *A. palmata* has low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we relied on information from the Final Management Report for evaluating the existing regulatory mechanisms for controlling threats to all corals. However, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. palmata*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. We also incorporate here, the evaluation of threats to this species conducted in the 2005 status review. Records confirm that *A. palmata* occurs in eight Atlantic ecoregions that encompass 26 kingdom's and countries' EEZs. The 26 kingdoms and countries are Antigua & Barbuda, Bahamas, Barbados, Belize, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, French Antilles, Grenada, Guatemala, Haiti, Kingdom of the Netherlands, Honduras, Jamaica, Mexico, Nicaragua, Panama, St. Kitts & Nevis, St. Lucia, St. Vincent & Grenadines, Trinidad and Tobago, United Kingdom (British Caribbean Territories), United States (including U.S. Caribbean Territories), and Venezuela. The regulatory mechanisms relevant to *A. palmata*, described first as a percentage of the above kingdoms and countries that utilize them to any degree, and second as the percentages of those kingdoms and countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 12 percent limited in scope), coral collection (50 percent with 27 percent limited in scope), pollution control (31 percent with 15 percent limited in scope), fishing regulations on reefs (73 percent with 50 percent limited in scope), managing areas for protection and conservation (88 percent with 31 percent limited in scope). The most common regulatory mechanisms in place for *A. palmata* are fishing regulations and area management for protection and conservation. However, half of the fishing regulations are limited in scope. General coral protection and collection laws, along with pollution control laws, are much less common regulatory mechanisms for the management of *A. palmata*. The 2005 status review and 2006 listing concluded that existing regulatory mechanisms are inadequate to control both global and local threats, and are contributing to the threatened status of the species, and we incorporate that analysis here.

Additionally, the public comments suggested that we did not fully consider the effects that conservation efforts have on the status of *A. palmata*. Therefore, conservation efforts are described as follows. Conservation efforts have been underway for *A. palmata* for a number of years. Of 60 *Acropora* restoration efforts identified in 14 Caribbean countries, 52 percent used *A. palmata*, including efforts in Belize, British Virgin Islands, Colombia, Curacao, Dominican Republic, Guadalupe, Jamaica, Mexico, Puerto Rico, Turks and Caicos, U.S. Virgin Islands, and Florida (Young *et al.*, 2012). SECORE, a conservation organization comprised of public aquariums, zoos, and researchers, holds annual workshops to accommodate sexual fertilization of *A. palmata* eggs collected from the wild, with the intent of rearing larvae for development of ex situ populations for conservation (Petersen *et al.*, 2008). However, to date, *A. palmata* colonies produced through in vitro fertilization have rarely been planted into the wild for restoration (but see Roik *et al.*, 2011; Szmant and Miller, 2005).

Restoration efforts involving *A. palmata* more typically re-attach fragments after physical disturbance such as storms or ship groundings (Bruckner and Bruckner, 2001; Garrison and Ward, 2008) or grow colonies in coral nurseries (Becker and Mueller, 2001; Bowden-Kerby and Carne, 2012; Johnson *et al.*, 2011) to outplant. Fast growth rates, branching morphology, and asexual reproduction through fragmentation make *A. palmata* an ideal candidate for active propagation, and there are a number of offshore nurseries that are producing corals for use in restoration and re-establishment of degraded populations. High survivorship (>70 percent) of coral fragments has been found within coral nurseries during the first year of propagation (Young *et al.*, 2012). Survival rates after transplanting are variable, ranging between 43 and 95 percent during the first year, and decreasing in some studies using non-nursery raised fragments to 0 to 20 percent after five years (Young *et al.*, 2012).

In conclusion, there are many conservation efforts aimed at increasing abundance and genetic diversity of *A. palmata* throughout the Caribbean. These efforts are important, but not enough to ensure conservation unless combined with efforts to reduce the underlying threats and causes of mortality (Young *et al.*, 2012). While conservation efforts will likely enhance recovery and conservation of *A. palmata* at small spatial scales, they are unlikely

to affect the status of the species, given the global nature of threats.

#### Vulnerability to Extinction

In 2006, *A. palmata* was listed as threatened, *i.e.*, likely to become in danger of extinction within the next 30 years, due to: (1) Recent drastic declines in abundance of the species that have occurred throughout its geographic range and abundances at historic lows; (2) the potential constriction of broad geographic ranges due to local extirpations resulting from a single stochastic event (*e.g.*, hurricanes, new disease outbreak); (3) limited sexual recruitment in some areas and unknown levels in most; and (4) occurrence of the Allee effect (in which fertilization success declines greatly as adult density declines).

The species was not listed as endangered, *i.e.*, currently in danger of extinction, because: (1) It was showing limited, localized recovery; (2) range-wide, the rate of decline appeared to have stabilized and was comparatively slow as evidenced by persistence at reduced abundances for the past two decades; (3) it was buffered against major threats by the large number of colonies, large geographic range, and asexual reproduction; and (4) as shown by the geologic record, the species has persisted through climate cooling and heating fluctuation periods over millions of years, whereas other corals have gone extinct.

In 2012, *A. palmata* was proposed for listing as endangered because information available since the original 2006 listing as threatened suggested: (1) Population declines have continued to occur, with certain populations of both species decreasing up to an additional 50 percent or more since the time of listing; (2) there are documented instances of recruitment failure in some populations; (3) minimal levels of thermal stress (*e.g.*, 30 degrees C) have been shown to impair larval development, larval survivorship, and settlement success of *A. palmata*; (4) near-future levels of acidification have been demonstrated to impair fertilization, settlement success, and post-settlement growth rates in *A. palmata*; (5) on average 50 percent of the colonies are clones, meaning the effective number of genetic individuals is half the total population size; (6) the species' ranges are not known to have contracted, but with continued declines local extirpations are likely, resulting in a reduction of absolute range size. Furthermore, we took into account that the BRT identified restriction to the Caribbean as a spatial factor increasing extinction risk, though, among other

things, exposure to high levels of human disturbance that result in pollution and breakage impacts. Also, while asexual reproduction (fragmentation) provides a source for new colonies (albeit clones) that can buffer natural demographic and environmental variability remains true, we believed that reliance on asexual reproduction is not sufficient to prevent extinction of the species. Last, the previous status review and listing determination underestimated the global climate change-associated impacts to *A. palmata* and *A. cervicornis*, based on our current knowledge of trends in emissions, likely warming scenarios, and ocean acidification. In particular, in the previous determination, we identified ocean acidification only as a factor that "may be contributing" to the status of two species, in comparison to our current understanding that ocean acidification is one of the three highest order threats affecting extinction risk for corals.

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic traits, threat susceptibilities, and consideration of the baseline environment and future projections of threats. Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species' abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. palmata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. The species has undergone substantial population decline and decreases in the extent of occurrence throughout its range due mostly to disease. Although localized mortality events have continued to occur, percent benthic cover and proportion of reefs where *A. palmata* is dominant have remained stable over its range since the mid-1980s. There is

evidence of synergistic effects of threats for this species including disease outbreaks following bleaching events. *Acropora palmata* is highly susceptible to a number of threats, and cumulative effects of multiple threats are likely to exacerbate vulnerability to extinction. Despite the large number of islands and environments that are included in the species' range, geographic distribution in the highly disturbed Caribbean exacerbates vulnerability to extinction over the foreseeable future because *A. palmata* is limited to an area with high localized human impacts and predicted increasing threats. *Acropora palmata* occurs in turbulent water on the back reef, fore reef, reef crest, and spur and groove zone in water ranging from 1 to 30 m in depth. This moderates vulnerability to extinction over the foreseeable future because the species occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute population abundance has been estimated as at least hundreds of thousands of colonies in both Florida and a portion of the U.S. Virgin Islands and is higher than the estimate from these two locations due to the occurrence of the species in many other areas throughout its range. *Acropora palmata* has low sexual recruitment rates, which exacerbates vulnerability to extinction due to decreased ability to recover from mortality events when all colonies at a site are extirpated. In contrast, its fast growth rates and propensity for formation of clones through asexual fragmentation enables it to expand between rare events of sexual recruitment and increases its potential for local recovery from mortality events, thus moderating vulnerability to extinction. Its abundance and life history characteristics, combined with spatial variability in ocean warming and acidification across the species' range, moderate vulnerability to extinction because the threats are non-uniform, and there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. palmata* was proposed for listing as endangered because of: High vulnerability to ocean warming (E), ocean acidification (E) and disease (C); high vulnerability to sedimentation (A and E) and nutrient over-enrichment (A and E); uncommon abundance (E); decreasing trend in abundance (E); low

relative recruitment rate (E); narrow overall distribution (E); restriction to the Caribbean (E); and inadequacy of regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. palmata* from endangered to threatened. We made this determination based on a more species-specific and holistic approach, including consideration of the buffering capacity of this species' spatial and demographic traits, and the best available information above on *A. palmata*'s spatial structure, demography, threat susceptibilities, and management. The combination of these factors indicates that *A. palmata* is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora palmata* is highly susceptible to ocean warming (ESA Factor E), disease (C), ocean acidification (E), sedimentation (A, E), nutrients (A, E), and predation (C) and susceptible to trophic effects of fishing (A), depensatory population effects from rapid, drastic declines and low sexual recruitment (C), and anthropogenic and natural abrasion and breakage (A, E). These threats are expected to continue and increase into the future. In addition, the species is at heightened extinction risk due to inadequate existing regulatory mechanisms to address local and global threats (D);

(2) *Acropora palmata* is geographically located in the highly disturbed Caribbean, where localized human impacts are high and threats are predicted to increase as described in the Threats Evaluation section. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Acropora palmata*'s abundance is still a fraction of what it was before the mass mortality in the 1970s and 1980s, and recent population models forecast the extirpation of the species from some locations over the foreseeable future.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. palmata*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of

extinction and thus does not warrant listing as Endangered because:

(1) While *A. palmata*'s distribution in the Caribbean increases its risk of exposure to threats as described above, its habitat includes back reef environments and turbulent water on the fore reef, reef crest, shallow spur and groove zone. It is most commonly found in depths of one to 12 m but is also found in depths up to 30 m. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will experience highly variable thermal regimes and ocean chemistry on local and regional scales at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections;

(2) *Acropora palmata*'s absolute abundance is at least hundreds of thousands of colonies based on estimates from two locations in its range. Absolute abundance is higher than estimates from these locations since *A. palmata* occurs in many other locations throughout its range. This absolute abundance allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section;

(3) Recent information indicates that proportions of Caribbean sites where *A. palmata* is present and dominant have stabilized;

(4) *Acropora palmata* has fast growth rates and high capacity to produce clones through asexual fragmentation, which can aid in local recovery from mortality events; and

(5) *Acropora palmata* shows evidence of resistance to bleaching from warmer temperatures in some portions of its range under some circumstances (e.g. Little Cayman).

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section and thus does not warrant listing as endangered at this time. Therefore, we withdraw our proposal to list *A. palmata* as endangered.

Progress has been made with *A. palmata*-specific conservation and restoration projects, albeit small-scale, and these projects are likely to increase in the future. Within some countries, *A. palmata*-specific conservation and restoration projects show promise for enhancing species recovery at very small spatial scales and facilitating the

persistence of the species in some areas in the face of continuing threats. Range-wide, a multitude of conservation efforts are already broadly employed specifically for *A. palmata*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species' status to the point at which listing is not warranted.

#### *Indo-Pacific Species Determinations*

Absolute abundance is approximated at a coarse scale in the Demographic Information sections for most of the Indo-Pacific species, based on a comparison of corrected data from Richards *et al.* (2008) and the distribution and abundance results from Veron (2014). Mean global census sizes for four species in this final rule (*Acropora jacquelineae*, *A. lokani*, *A. speciosa*, and *A. tenella*) are provided in Richards *et al.* (2008). An error in the global census size formula (Richards *et al.* 2008, Supplementary Information file Methods\_S1) resulted in 1,000-fold under-estimates of global census size in Richards *et al.* (2008) for these four species, as confirmed by NMFS with the author in 2013. Richards *et al.*'s (2008) corrected census results were compared with Veron's ecoregion distribution and semi-quantitative abundance results to derive coarse approximations of absolute abundance. For each species, the resulting absolute abundance is described as either "at least millions of colonies," or "at least tens of millions of colonies" (NMFS, 2014). Although this comparison produces only very general approximations of abundance, large scale estimates are sufficient for considering whether population size provides buffering capacity within the context of our listing determinations.

#### *Genus Millepora*

##### Genus Introduction

The SRR and SIR provided no genus-level introduction information for *Millepora*. However, they did provide the following information on reproduction in the genus. *Millepora* species are hydrozoans, thus their life history cycle includes a medusae stage, a free-swimming, bell-shaped form ("jellyfish") that produces gametes. Reproduction is seasonal. The adult coral colonies produce tiny medusae, which release gametes within a few days after being released from the colony. Medusae are in separate sexes,

and the milleporid medusae of some species live for only a few hours. The gametes of some milleporids can become mature in 20 to 30 days, more rapidly than for many scleractinians. Hydrozoan corals of the genus *Millepora* are the only reef-building corals with medusae as part of their life history. Branching and columnar forms of *Millepora* are subject to fragmentation and may use this mechanism to reproduce asexually; unlike scleractinian corals, the survival of *Millepora* fragments may not be size-dependent.

There is only one genus in the Family Milleporidae, the genus *Millepora*. About 16 species of *Millepora* are currently considered valid. While all coral species in this final rule are “cnidarians” (Phylum Cnidaria), *Millepora* are “hydrozoans” (Class Hydrozoa, which includes jellyfish), whereas all other species in this rule are “scleractinians” (Class Anthozoa, Order Scleractinia). Like other reef-building corals, *Millepora* species contain zooxanthellae, produce calcium carbonate skeletons, may grow fast, and are thus major contributors to the physical structure of coral reefs. Unlike other reef-building corals, the surfaces of *Millepora* colonies are covered with tiny polyps that look like hairs, containing stinging cells to capture prey. Most species can sting humans with the same stinging cells, hence the common name “fire corals.” Colonies of *Millepora* species are encrusting, branching, foliose (leafy), or combinations of these forms. The biology and ecology of *Millepora* are reviewed in Lewis (2006).

#### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Millepora*. The genus *Millepora* has been called a bleaching “loser.” *Millepora* species are ranked as the most susceptible to bleaching in response to high seawater temperatures of any of the 40 genera or other categories of hermatypic corals in the Great Barrier Reef. The genus has been reported to be highly susceptible to bleaching in the western Indian Ocean and appears to have experienced local extirpations in the tropical eastern Pacific. Low bleaching occurred in *Millepora* in Moorea during the 1991 event, but elevated temperatures can also kill *Millepora* even in the absence of bleaching. At elevated temperatures, *Millepora dichotoma* showed decreased zooxanthellae density, changes in chlorophyll concentrations, and decreased calcification. *Millepora* species are among the first to bleach and

die in response to high temperature events, but they also seem to have a high capacity for quickly recovering by recruiting new colonies.

*Millepora* have been observed with a greater than 20 percent prevalence of skeleton-eroding-band disease in the Red Sea. There are reports of black-band disease on *Millepora* on the Great Barrier Reef and white plague in Florida. Few other reports exist for the Pacific, and Caribbean congeners have been observed with a small number of diseases.

*Millepora* species are known to be preyed on by the crown-of-thorns seastar *Acanthaster planci*, although they are less preferred prey than acroporids and perhaps most scleractinians. *Millepora* species are also preyed on by the polychaete *Hermodice carunculata*, the nudibranch mollusk *Phyllidia*, and filefish of the genera *Alutera* and *Cantherhines*.

Although *Millepora* species tend to favor relatively clear water with low rates of sedimentation, they were reported to be among the last 17 out of 42 genera to drop out along a gradient of increasing rate of sedimentation. *Millepora* also showed increased relative abundance and colony size on sediment impacted reefs in Kenya. Though little is known about effects of nutrients on Pacific *Millepora*, Caribbean congeners were found to decrease in percent cover on eutrophic reefs in Barbados.

The genus *Millepora* has been involved in international trade from Indonesia, Solomon Islands, and Fiji with reported exports between 200 and 3000 pieces per year in the years 2000–2008. Reported exports from Vietnam, Malaysia, and Tonga were less than 1000 pieces per year in the same time period.

Public comments did not provide any information on the genus *Millepora*. We gathered supplemental information on the susceptibilities of *Millepora* species to some threats, including the following. High bleaching and mortality in *Millepora* species has been reported in response to warming events. All *Millepora* colonies on reef flats of two islands in the Thousand Islands of Indonesia died in the 1983 El Nino mass bleaching (Brown and Suharsono, 1990). In contrast, *Millepora* colonies showed no evidence of bleaching in Moorea, French Polynesia in the 1991 bleaching event other than occasional mild paling (Gleason, 1993). In Palau in 2000, some mortality was seen among *Millepora* colonies (Bruno *et al.*, 2001). Almost all *Millepora* colonies in study sites outside of marine protected areas in Kenya were killed by mass bleaching in 1998, but in

protected sites there was actually an increase in *Millepora* colonies (McClanahan *et al.*, 2001). *Millepora* colonies had a bleaching index of 23.06 for eight countries in the western Indian Ocean in 1998–2005, which was 12th highest of the 45 genera recorded, and 56 percent of the highest value (McClanahan *et al.*, 2007a). *Millepora* had the highest bleaching level of any genus in Australia, and a moderately high level in Kenya in 1998 (Pandolfi *et al.*, 2011). *Millepora* colonies in Okinawa, Japan, experienced sharp drops in populations following the 1998 and 2010 mass bleaching episodes (Hongo and Yamano, 2013). At Mauritius in a bleaching event in 2004, *Millepora* had a bleaching index of 35, the second highest of the 32 genera recorded (McClanahan *et al.*, 2005a). *Millepora* colonies had the highest level of bleaching among the corals of the Socotra islands of Yemen, just outside the Red Sea, in 1998 (DeVantier *et al.*, 2005).

While *Millepora* species are among the most susceptible of all reef-building corals to warming-induced bleaching, they also often recover more quickly than scleractinians, opportunistically overgrowing bleached colonies. Such relatively rapid recovery by *Millepora* species from bleaching events has been observed in both the Indo-Pacific and Caribbean, and is facilitated by short colony life and ready regeneration of fragments (Lewis, 2006). At a foreereef site in the Marquesas Islands, French Polynesia, *Millepora platyphyllia* overgrew dead scleractinian colonies to form a large monospecific stand (Andréfouët *et al.*, 2014). At a back-reef site on Ofu Island, American Samoa, following a bleaching event in 2002 that killed almost all *Millepora dichotoma*, colonies appeared and became fairly common within a few years (Doug Fenner, personal comm.). Following both the 1982–83 and 1997–98 warming events, *Millepora intricata* was extirpated from shallow water in the eastern Pacific, but showed recovery within several years, likely because of recolonization from deep water (Smith *et al.*, in press). In contrast, a long-term study showed that three *Millepora* species were “long-term losers” (*i.e.*, populations decreased to zero, and remained there) following mass bleaching events in Japan in 1998 and 2010, while two other species of *Millepora* were “neither winners nor losers” (*i.e.*, changes in their populations were not significant) (van Woesik *et al.*, 2011).

*Millepora* colonies in the Great Barrier Reef had low susceptibility to Skeletal Eroding Band (the most prevalent

disease on the GBR), with a prevalence of 0.4 percent out of 4,068 colonies surveyed (Page and Willis, 2007).

Several recent studies compare vulnerabilities across genera or species for a large number of reef-building coral species, and the results of these studies are summarized below with regard to *Millepora*. Foden *et al.* (2013) developed a framework for evaluating the vulnerability of corals (and birds and amphibians) to extinction due to climate change. They categorized all of the six species of *Millepora*, which they reported on as having a low vulnerability to climate change. A field study that tracked the responses of 46 reef-building coral species in southern Japan from 1997 to 2010 through two bleaching events in 1998 and 2001 rated three *Millepora* species as neither winners nor losers, and two *Millepora* species as long term losers. Three of the *Millepora* species were branching and all three branching species were “long term losers,” one species is encrusting and one produces plates, and those two species were neither long term winners or losers (van Woesik *et al.*, 2011). There is no information available on the effects of any other threat for *Millepora* species.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information we can make the following inferences about the susceptibilities of an unstudied *Millepora* species to ocean warming, disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, or collection and trade. The large majority of studies report that *Millepora* species are highly susceptible to thermal stress and bleaching, but vulnerability may be moderated by the capacity for rapid recovery in some species. An unstudied species of *Millepora* such as *M. tuberosa* can be predicted in a bleaching event to not be a “winner” in the long term, but it cannot be predicted whether they will be a long term loser, or neither a winner or loser. Thus, an unstudied species of *Millepora* is likely to be highly susceptible to ocean warming. Based on the above information, an unstudied species of *Millepora* is likely to have some susceptibility to disease, sedimentation, nutrients, and predation.

The SRR rated ocean acidification as “medium-high” importance, the third most important threat to corals overall, because of the likely effects of decreasing ocean pH on coral calcification and reproduction. Thus, an unstudied *Millepora* species is likely to have some susceptibility to ocean

acidification. The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Millepora* species is likely to have some susceptibility to the trophic effects of fishing. The SRR rated sea-level rise as “low-medium” importance to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, most likely to sediment-tolerant assemblages and slower growing species. Because *Millepora* are not generally sediment-tolerant and are faster growing species, an unstudied *Millepora* species is likely to have some susceptibility to sea-level rise. The SRR rated ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall, and this threat is addressed at both the genus and species levels in the SRR. Because *Millepora* species are widely collected and traded, an unstudied *Millepora* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Millepora* species is likely to be highly susceptible to ocean warming (*i.e.*, thermal stress, leading to warming-induced bleaching), and to have some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### *Millepora foveolata*

##### Introduction

The SRR and SIR provided the following information on *M. foveolata*'s morphology and taxonomy. Colonies of *Millepora foveolata* form thin encrusting laminae that adhere closely to the underlying substrata. *Millepora foveolata* is sometimes confused with the similarly encrusting *Millepora exaesa*.

The public comments did not provide any new or supplemental information on *M. foveolata*'s morphology and taxonomy. However, we gathered

supplemental information on *M. foveolata* that indicates a very high level of species identification uncertainty, because its distinctive features are very small and difficult to learn. In addition, no pictures of live colonies have been published of this species. Corals of the World (Veron, 2000) does not include non-scleractinians such *Millepora* species, making it very difficult to obtain reliable reference material. Many coral experts also ignore *Millepora* species, but even those that are interested in them have little opportunity to hone identification skills because the species is quite rare and not often encountered on surveys. Thus, even though *M. foveolata* is considered a valid species, and there are no known taxonomic uncertainty issues, the species is so difficult to identify in the field that there is very little reliable information available for this species (Fenner, 2014b). Thus, a high proportion of the information on *M. foveolata*'s distribution and abundance information in the SRR or SIR is likely based on inaccurate field identifications, thus we do not consider this information to be sufficiently reliable, and are unable to provide a reliable species description for *M. foveolata* in this final rule.

##### Listing Determination

In the proposed rule, *M. foveolata* was proposed for listing as endangered because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

Based on the lack of information on *M. foveolata*'s distribution, abundance, and threat vulnerabilities due to this species' identification uncertainty, we believe there is not sufficient evidence to support a listing determination of threatened or endangered. Therefore, we find that listing is not warranted at this time.

#### *Millepora tuberosa*

##### Introduction

The SRR and SIR provided the following information on *M. tuberosa*'s morphology and taxonomy. *Millepora tuberosa*'s colony morphology consists of thin (about 1 mm at encrusting peripheral margins) to moderately thick (3 cm or more in the central regions of larger colonies) encrusting laminae that closely adhere to the underlying substrata. They are always encrusting

and so do not make vertical plates or branches, although they can be nodular or lumpy, especially when they encrust rubble. *Millepora tuberosa* is often found as small colonies (5 to 30 cm diameter) but can be greater than one meter in diameter. The SIR reports that several authors have commented that people could inadvertently misidentify *M. tuberosa* colonies as crustose coralline algae, and the SIR reports it can look similar to *Psammocora nierstrazi* if they have similar color. There is some taxonomic uncertainty, as *M. tuberosa* has been synonymized with *Millepora exaesa* in one review. The problem may be that the skeletons are quite similar, but the living colonies appear quite different, mainly in color; *M. tuberosa* is a wine color, unlike other *Millepora* species.

The public comments and information we gathered did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, which confirmed that *M. tuberosa* has moderate taxonomic uncertainty, but is easily identified. *Millepora tuberosa* is distinctive and not difficult to identify by experts, thus the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *M. tuberosa*'s distribution, habitat, and depth range. *Millepora tuberosa* is known from Mauritius, Taiwan, Mariana Islands, Caroline Islands, American Samoa, and New Caledonia. The species occurs in a broad range of habitats on the reef slope, reef crest, and back-reef, including but not limited to lower reef crests, upper reef slopes, and lagoons, from 1 to at least 12 m depth.

Public comments and information we gathered provided new or supplemental information on *M. tuberosa*'s distribution. One public comment stated *M. tuberosa* has been reported from a variety of sources suggesting that its range extends from that shown in the proposed rule westward to Madagascar, indicating a broader distribution than shown in the proposed rule. We gathered supplemental information, including results from surveys carried out from 2005 to 2014 in New Caledonia, American Samoa, the Northern Mariana Islands, Nauru, Tonga, and the Chagos Islands, that confirmed the occurrence of *M. tuberosa* in the first three areas but did not find it in the latter three areas (D. Fenner, personal comm.). Many experts, including Veron, do not record the

presence of *Millepora* species, thus the small number of reliable observations for this species likely indicates under-reporting rather than a reflection of its actual distribution or overall abundance. However, surveys by *Millepora* experts have not found the species at all coral reef sites surveyed within the areas encompassed by its known locations. Thus we conclude that the available information suggests a patchy range bounded by east Africa, Taiwan, Mariana Islands, Caroline Islands, American Samoa, and New Caledonia, and that the species' range makes up approximately one third to one half of the coral reef areas within the Indo-Pacific.

#### Demographic Information

The SRR and SIR provided the following information on *M. tuberosa*'s abundance. The SRR stated that the species is most often reported as occasional, but in Guam it is predominant in an area of lagoonal reef south of Agat Boat Harbor. The SIR cited several sources of information not available in the SRR, and concluded that the species' abundance should be considered common.

The public comments did not provide any new or supplemental information on *M. tuberosa*'s abundance. We gathered supplemental information, including abundance results from surveys conducted in New Caledonia, American Samoa, and the Northern Mariana Islands between 2005 and 2013. In New Caledonia, 87 sites were surveyed from 2006 to 2009, and only a single colony of *M. tuberosa* was found. At 67 sites surveyed in American Samoa from 2005 to 2010, *M. tuberosa* was found at 18 sites (of the sites, 31 were on Tutuila, and the species was found at 13 of them). At 22 sites surveyed in the Northern Mariana Islands in 2013, *M. tuberosa* was found at three sites (D. Fenner, personal comm.). At sites where *M. tuberosa* has been actively surveyed (*i.e.*, by coral abundance monitoring programs that includes *Millepora* experts), the available information shows wide variability in the species' abundance, from dominant or common (Guam) to uncommon (Tutuila, Northern Mariana Islands) to rare (New Caledonia). Based on the available information, we conclude that *M. tuberosa*'s overall abundance is common or uncommon overall, but locally rare.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *M. tuberosa*, the overall decline in abundance ("Percent Population Reduction") was estimated

at 59 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 22 percent (Carpenter *et al.*, 2008). This estimated decline is approximately 50 percent higher than most other Indo-Pacific species included in the Carpenter paper, apparently because of the combined restricted geographic and depth ranges. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *M. tuberosa* probably occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The public comments and information we gathered did not provide additional biological information on *M. tuberosa*.

#### Susceptibility to Threats

The SRR and SIR provided species-specific information on the susceptibility of *M. tuberosa* to sedimentation, predation, and secondary effects of heavy fishing pressure. The relatively high abundance of this species on Guam suggests it is resistant to those threats. Genus-level information is provided for the effects on *Millepora* of ocean warming, disease, predation, land-based sources of pollution (*i.e.*, sedimentation, nutrients, toxins, and salinity), and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *M. tuberosa*. The threat susceptibility and exposure information from the SRR and SIR was interpreted in the proposed rule for *M. tuberosa*'s vulnerabilities to threats as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, acidification, trophic effects of fishing, nutrients, and

low vulnerabilities to predation, sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *M. tuberosa*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Millepora tuberosa* has been rated as moderately or highly susceptible to bleaching but not coral disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Some colonies in American Samoa and Guam have been observed to have a discolored yellow area around part of the perimeter, which appeared to be a non-lethal disease (not all colonies had it, and no mortality was seen. No other disease was seen (Fenner, 2014a). There is no other species-specific information for the exposure or susceptibility of *M. tuberosa* to any threat. Based on information provided in the genus description above, *M. tuberosa* is likely to be highly susceptible to ocean warming, and has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on regulatory mechanisms or conservation efforts for *M. tuberosa*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis.

Veron's updated report on the listed coral species and their occurrence in various ecoregions (Veron, 2014) did not include *M. tuberosa*. To determine what countries the species occurs in we used the SRR, IUCN Red List of Threatened Species, and other sources where the species has been confirmed (Fenner, 2011) and conclude that the species occurs in a minimum of six countries' EEZs. Those six countries are the Federated States of Micronesia, France (New Caledonia), Mauritius, Palau, Taiwan, and the United States (CNMI, Guam, American Samoa). As noted in the Spatial Information paragraph above, it is likely the species occurs in a number of other countries, but we cannot determine which ones at this time, thus this management analysis is limited to the six countries where the species has been confirmed.

The regulatory mechanisms available to *M. tuberosa*, described first as a percentage of the above countries that utilize them to any degree, and second

as the percentage of those countries whose regulatory mechanisms are limited in scope, are as follows: General coral protection (33 percent with none limited in scope), coral collection (67 percent with 17 limited in scope), pollution control (33 percent with 17 percent limited in scope), fishing regulations on reefs (100 percent with 17 percent limited in scope), managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *M. tuberosa* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat utilized. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *M. tuberosa*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate, based on genus-level information, is the primary threat of extinction for *M. tuberosa*, which was compounded by the disjunct geographic range. The SRR also stated that factors that potentially reduce the extinction risk are that *M. tuberosa* might be more common than previously observed, and that like other *Millepora* species, it likely has a high capacity for recovering from bleaching.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. tuberosa*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic

distribution, based on the available information, includes patchy areas from the western Indian Ocean across the western and central Pacific, as far east as American Samoa. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from zero to at least 12 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes lower reef crests, upper reef slopes, and lagoons, which moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. While the species is locally rare, its overall abundance is common or uncommon. Thus, its overall abundance, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *M. tuberosa* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); narrow overall

distribution (based on narrow geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. tuberosa* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *M. tuberosa*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Millepora tuberosa*'s distribution stretches across the Indian Ocean and most of the Pacific Ocean and is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Millepora tuberosa*'s abundance is described as common or uncommon overall which, in terms of relative abundance of corals and in combination with the size of its range, indicates this species likely numbers in the tens or hundreds of millions of colonies, at least. This provides buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high

importance threats, the combination of these biological and environmental characteristics indicates that the species possesses significant buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that *M. tuberosa*'s extinction risk may increase in the future if global threats continue and worsen in severity, likely resulting in the continued decline of this species into the future. As the species experiences reduced abundance or range constriction of a certain magnitude, its ability to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *M. tuberosa* is not warranted for listing at this time under any of the listing factors.

#### Genus *Seriatopora*

##### Genus Introduction

The family Pocilloporidae includes three genera: *Pocillopora*, *Seriatopora*, and *Stylophora*. *Seriatopora* contains six species, all occurring in the Indo-Pacific (Veron, 2000). *Seriatopora* species have branching colonies. The SRR and SIR provided no genus-level introductory information on *Seriatopora*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Seriatopora*. Species in the genus *Seriatopora* are highly susceptible to bleaching across regions, including Micronesia the GBR, and the western Indian Ocean. The genus *Seriatopora* is known to be susceptible to predation by snails and the crown-of-thorns seastar, *Acanthaster planci*. The genus *Seriatopora* has been heavily traded, primarily from Fiji and Indonesia (and occasionally the Philippines and Taiwan). Many records are at the genus level; trade was heavy in the mid-1980s (exceeding 134,000 pieces in 1987). *Seriatopora hystrix* is the most heavily exploited species, although *Seriatopora caliendrum* is also exported.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Seriatopora*. We gathered supplemental information, which provided the following. There are several reports of high bleaching and

mortality in *Seriatopora* species in response to warming events. In response to the 1998 warming event, *Seriatopora* colonies in Palau had high levels of bleaching with high mortality (Bruno *et al.*, 2001). In response to the same warming event, over half of *Seriatopora* colonies in study sites within Kenyan marine protected areas were killed by mass bleaching (McClanahan *et al.*, 2001). A large study of the bleaching responses of over 100 coral species on the GBR to the 1998 bleaching event included one *Seriatopora* species, *Seriatopora hystrix*. For this species, approximately 40 percent of the observed colonies were bleached, resulting in *S. hystrix* being more affected than most of the Pocilloporidae and Acroporidae species in the study, and one of the 20 most affected species in the entire study (Done *et al.*, 2003b).

In response to a 2008 bleaching event in Papua New Guinea, two Pocilloporidae species (including *S. hystrix*) and 14 Acroporidae species were monitored, and each species' relative susceptibility to bleaching was evaluated in relationship to the other species in the study. Nine of the 16 species, including *S. hystrix*, had moderate susceptibility to bleaching, while five species were rated as severe or high susceptibilities, and two as low. Of the 139 *S. hystrix* colonies monitored in the study, 126 bleached (Bonin, 2012). In response to a 2004 warming event in Mauritius, the genus *Seriatopora* was the most bleached of the 32 genera recorded (McClanahan *et al.*, 2005b). In eight countries in the western Indian Ocean in 1998–2005, the *Seriatopora* genus had a bleaching index of 32, the fourth highest of the 45 genera recorded, and 75 percent of the highest value (McClanahan *et al.*, 2007a).

McClanahan *et al.* (2007a) calculated a relative extinction risk score based on bleaching for genera of corals in the western Indian Ocean. The index of extinction risk was proportional to the degree of bleaching and inversely proportional to the abundance and number of reefs on which a taxon was found. The index of extinction risk for *Seriatopora* was the eighth highest out of 47 genera, with a score of 0.46 based on a scale of zero to one, with one being the score of the highest extinction risk.

With regard to disease, two reports from the GBR provide contrasting information regarding the susceptibilities of *Seriatopora* species to various coral diseases. One study found that Black Band Disease was nearly absent on colonies of *Seriatopora* species (Page and Willis, 2006). In contrast, colonies of *Seriatopora* species

had high susceptibility to Skeletal Eroding Band, with a prevalence of 5.8 percent. Skeletal Eroding Band is the most prevalent disease on the GBR (Page and Willis, 2007). *Seriatopora* in Indonesia was reported to have no diseases (Haapkyla *et al.*, 2007). There is no information available on the effects of any other threat for *Seriatopora* species.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Seriatopora* species to ocean warming, disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance to corals. These were rated as the three most important threats to reef-building corals overall. All studies on thermal stress in *Seriatopora* report high levels of bleaching in response to warming events. Thus, we conclude that *Seriatopora* likely has high susceptibility to ocean warming. Studies reported that one disease did not infect *Seriatopora*, but another did at high prevalence, and no diseases infected it in Indonesia. Thus, we conclude that *Seriatopora* has some susceptibility to disease. Although there is no other genus-level or species-specific information on the susceptibilities of *Seriatopora* species to ocean acidification, the SRR rated it as “medium-high” importance to corals. Thus, we conclude that an unstudied *Seriatopora* species has some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, we conclude that an unstudied *Seriatopora* species has some susceptibility to the trophic effects of fishing.

Although there is no genus-level or species-specific information on the susceptibilities of *Seriatopora* species to sedimentation or nutrients, the SRR rated both threats as “low-medium”

importance to corals. Thus, we conclude that an unstudied *Seriatopora* species has some susceptibility to these threats. Sea-level rise was also rated as “low-medium” importance to corals. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Seriatopora* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. *Seriatopora* is preyed on by both snails and crown-of-thorns starfish. Thus we conclude that *Seriatopora* has some susceptibility to predation. *Seriatopora* is heavily traded, thus we conclude that *Seriatopora* has some susceptibility to collection and trade.

In conclusion, an unstudied *Seriatopora* species is likely to be highly susceptible to ocean warming, and to have some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### *Seriatopora aculeata*

##### Introduction

The SRR and SIR provided the following information on *S. aculeata*'s morphology and taxonomy. Morphology was described as thick, short, tapered branches, usually in fused clumps. The taxonomy was described as somewhat uncertain, because genetic studies have not corresponded well with morphology for *S. aculeata* and other species of *Seriatopora*. Similar species, *Seriatopora stellata* and *S. hystrix*, can have similar branching structures in shallow, exposed reef flats.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there is a moderate level of taxonomic uncertainty for *S. aculeata*, and that there is a moderate level of species identification uncertainty for this species. Veron (Veron, 2014) states that *S. aculeata* is sometimes confused with *S. stellata*, but Veron (Veron, 2000; Veron, 2014) continues to consider it a valid species, and we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *S. aculeata*'s

distribution, habitat, and depth range. *Seriatopora aculeata* is distributed from Australia, Fiji, Indonesia, Japan, Papua New Guinea, and Madagascar to the Marshall Islands. The SRR and SIR described *S. aculeata*'s habitat as shallow reef environments, and its depth range as three to 40 meters. The SIR reported it in Guam and the Northern Marianas.

The public comments and information we gathered provided supplemental information on the distribution and habitat of *S. aculeata*. One public comment stated that in Guam, the few specimens of *S. aculeata* observed since 2004 were found in areas with high rates of sedimentation. Thus, based on all the available information, *S. aculeata*'s habitat can be summarized as follows: The species occurs in a broad range of habitats on the reef slope and back-reef, including but not limited to upper reef slopes, mid-slope terraces, lower reef slopes, reef flats, and lagoons. Supplemental information provided the following. Veron (2014) provides an updated, much more detailed range map for this species than the maps used in the SRR. Veron reports that *S. aculeata* is confirmed in 19 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional seven.

##### Demographic Information

The SRR and SIR provided the following information on *S. aculeata*'s abundance. *Seriatopora aculeata* has been reported as uncommon.

The public comments did not provide any new or supplemental information on *S. aculeata*'s abundance, but the supplemental information provided the following. Veron (2014) reports that *S. aculeata* occupied 10.3 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.70 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “common,” and overall abundance was described as “uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *S. aculeata*, the overall decline in abundance (“Percent Population Reduction”) was estimated

at 37 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *S. aculeata* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *S. aculeata*'s life history. Little is known of *S. aculeata*'s life history. The much more common species, *S. hystrix*, is a simultaneous hermaphrodite that reproduces sexually via brooded larvae. The public comments and information we gathered provided no additional biological information.

#### Susceptibility to Threats

To describe *S. aculeata*'s threats, the SRR and SIR provided genus-level information for the effects on *Seriatopora* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *S. aculeata*, except for a single export record from Indonesia for four pieces of the species in 2008. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *S. aculeata*'s vulnerabilities as follows. High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, nutrients, and predation; and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments provided some supplemental information on *S.*

*aculeata*'s threat susceptibilities. One comment stated that the depth range for *S. aculeata* on the reef slopes of Guam are coincident with those of the crown-of-thorns starfish, both of which are below 5 to 7 meters depth, exposing *S. aculeata* to predation. *Seriatopora aculeata* has been rated as not moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.* 2008). There is no supplemental species-specific information for the susceptibility of *S. aculeata* to any threat. Based on information provided in the *Seriatopora* genus description above, *S. aculeata* is likely to be highly susceptible to ocean warming, and is likely to have some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *S. aculeata* to the threats.

#### Regulatory Mechanisms.

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *S. aculeata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *S. aculeata* occurs in 19 Indo-Pacific ecoregions that encompass 10 countries' EEZs. The 10 countries are Federated States of Micronesia, France (French Pacific Island Territories), Indonesia, Japan, Palau, Papua New Guinea, Philippines, Solomon Islands, Timor-Leste, and the United States (CNMI, Guam, PRIAs). The regulatory mechanisms available to *S. aculeata*, described first as a percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms are limited in scope, are as follows: General coral protection (40 percent with none limited in scope), coral collection (70 percent with 20 percent limited in scope), pollution control (30 percent with 20 percent limited in scope), fishing regulations on reefs (100 percent with none limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *S. aculeata* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also heavily utilized for the species.

General coral protection and pollution control laws are less common regulatory mechanisms for the management of *S. aculeata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the primary factor that increases the potential extinction risk is its high bleaching susceptibility. The genus *Seriatopora* is heavily traded, but not often identified to species. Heavy use in the aquarium trade implies the potential for local extirpation for this usually uncommon species.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *S. aculeata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited to parts of the Coral Triangle and the western equatorial Pacific Ocean. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range of 40 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. The species

occurs in a broad range of habitats on the reef slope and back-reef, including but not limited to upper reef slopes, mid-slope terraces, lower reef slopes, reef flats, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. There is not enough information about its abundance to determine if it moderates or exacerbates extinction. It is common and has at least millions of colonies, but the great majority of the population is within an area expected to be severely impacted by threats over the foreseeable future. While depth distribution and habitat variability moderate vulnerability to extinction, the combination of its geographic distribution and high susceptibility to ocean warming are likely to be more influential to the status of this species over the foreseeable future, because of the projected severity of ocean warming throughout the species' range in the foreseeable future, and its high susceptibility to this threat.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *S. aculeata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we maintain the listing determination for *S. aculeata* as threatened. Based on the best available information provided above on *S. aculeata*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Seriatopora aculeata* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C) ocean acidification (E), trophic effects of fishing (A), nutrients (A, E), and collection and trade (B). In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D); and

(2) *Seriatopora aculeata*'s distribution is constrained to the Coral Triangle and western equatorial Pacific, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *S. aculeata*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While half of *S. aculeata*'s range is within the Coral Triangle which increases its extinction risk as described above, its habitat includes various shallow reef environments down to 40 meters. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, at local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat sub-section and Threats Evaluation section. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species;

(2) *Seriatopora aculeata* occurs down to at least 40 m so its depth range will provide some refugia from threats because deeper areas of its range will usually have lower irradiance than surface water, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs; and

(3) *Seriatopora aculeata*'s absolute abundance is at least millions of colonies, which allows for variation in the responses of individuals to threats to

play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *S. aculeata*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Genus Acropora, Indo-Pacific*

##### Genus Introduction

The SRR and SIR provided an introduction to Indo-Pacific *Acropora*, covering geological history, taxonomy, life history, and threat susceptibilities of the genus as a whole. *Acropora* colonies are usually branching, bushy, or plate-like, rarely encrusting or submassive. *Acropora* is by far the largest genus of corals with over 150 species, and dominates many reefs, making *Acropora* the most important single genus of corals in the world. Almost all species of *Acropora* are in the Indo-Pacific.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on genus-level threat susceptibilities for Indo-Pacific *Acropora*. *Acropora* are widely reported to be more sensitive to bleaching in response to high temperatures than other coral genera. Some studies report branching species of *Acropora* to bleach more than table species, but other studies do not find this. Bleaching mortality in *Acropora* can be very severe. Larval connectivity and survival of partially-dead colonies are probably

important in population recovery. Bleaching of *Acropora* has been followed by disease outbreaks and by reduced fecundity for a year or two. Fertilization and larval stages of *Acropora* are particularly sensitive to high temperatures.

Ocean acidification decreases the rate of calcification in *Acropora*. For one species of *Acropora* in the Caribbean, decreases in growth rates on reefs over decades has been attributed to acidification. Acidification negatively affects a variety of stages of reproduction in *Acropora*.

*Acropora* are vulnerable to most of the diseases that infect coral, and are more commonly affected by acute and lethal diseases (“white diseases” or tissue loss) than other corals. Such lethal diseases have been the major cause of the loss of most *Acropora* in the Caribbean. The reduction of coral populations by disease leads to negative synergisms, as it reduces *Acropora* reproductive output and can lead to recruitment failure, making population recovery very difficult.

*Acropora* are preferred prey for most predators that prey on coral, including the crown-of-thorns starfish, a variety of snails including *Drupella*, butterflyfish, and fireworms. Individual territorial butterflyfish can take 400–700 bites per hour, and butterflyfish densities can be 50–70 per 1000m<sup>2</sup>, demonstrating possible intense predation on *Acropora*. *Acropora* have low carbon and protein content in their tissues so a low nutrient value, yet are still preferred prey. This suggests that instead of investing in chemical defenses against predation, *Acropora* invests its energy in rapid growth. However, when coral populations are greatly reduced, the predatory pressure is increased on colonies, and can exert a positive-feedback effect (Allee Effect or depensation) that makes populations unstable and can lead to collapse or lack of recovery.

In general, *Acropora* species are relatively more susceptible to the effects of sedimentation than many other reef-building corals. Though certain growth forms (e.g., cylindrical branches) may be more effective at passive sediment rejection than others, *Acropora* are generally not adept at actively removing sediment. *Acropora* have also shown particular sensitivity to shading, an effect of turbid waters resulting from sedimentation. In addition, adult colonies of *Acropora* have reportedly shown impacts from sedimentation especially during reproduction.

*Acropora* species are also relatively more susceptible to the effects of nutrients, especially with regard to

reproduction and recruitment. Elevated nutrients have been shown to reduce fertilization success, survival, and settlement of *Acropora* larvae. Further, iron-rich “red” soils typical of tropical islands, as well as other chemicals in run-off, interfere with synchronization of spawning among colonies, egg-sperm recognition and interactions, fertilization, and embryo development.

*Acropora* species are heavily collected and widely traded internationally. Trade quotas and reports are typically listed only at the genus level, making any species-specific inferences with regard to this threat very difficult.

The public comments did not provide any supplemental information on genus-level threat susceptibilities for Indo-Pacific *Acropora*. However, we gathered supplemental information, which provides the following genus-level information on threat susceptibilities of Indo-Pacific *Acropora* for ocean warming, disease, ocean acidification, and predation. With regard to susceptibility to ocean warming, Fisk and Done (1985) report bleaching patterns on a site on the Great Barrier Reef in 1982 to 1983. Most species of *Acropora* in shallow water had significant mortality, but *Acropora hyacinthus* did not. Mortality varied by species and site. Brown and Suharsono (1990) reported that the 1983 El Niño caused a mass bleaching event in the Thousand Islands, Indonesia. The mass bleaching event killed all *Acropora* (22 species) in the transects on the reef flats of two islands (Brown and Suharsono, 1990). Gleason (1993) reported that *Acropora* was the second most affected genus by bleaching (*Montastraea* was the most affected) in Moorea, French Polynesia in 1991, and that it had the greatest mortality. McClanahan *et al.* (2001) report that almost all *Acropora* in study sites in Kenya were killed by mass bleaching in 1998. Kayanne *et al.* (2002) reported that in 1998 in the Ryukyu Islands of Japan, branching *Acropora* was susceptible to bleaching and mortality was high. The branching species in this study were primarily *A. formosa* (= *A. muricata*) and also *A. pulchra* and *A. palifera* (= *Isopora palifera*). Hughes *et al.* (2003) reported that 11 *Acropora* species ranged from 0 to 100 percent affected by bleaching in Raiatea, French Polynesia, in 2002. Done *et al.* (2003b) reported that 46 *Acropora* species ranged from 0 to 44 percent affected by bleaching on the Great Barrier Reef in 2003.

Based on a bleaching index scaled from 0 to 100 (with 0 as no bleaching and 100 as complete bleaching), McClanahan *et al.* (2004) reported that

during mass bleaching in 1998, *Acropora* had a higher index in Kenya (80) than in Australia (40); temperatures were higher in Kenya. *Acropora* in Mauritius had an index of 39, the fifth highest of the 32 genera recorded, following a 2004 bleaching event (McClanahan *et al.*, 2005a). *Acropora* had an index of 28.9 for eight countries in the western Indian Ocean in 1998–2005, which was fifth highest of the 45 genera recorded (McClanahan *et al.*, 2007a). The abundance of *Acropora* after 1998 in the western Indian Ocean decreased strongly in proportion to the number of degree heating weeks in 1998 (McClanahan *et al.*, 2007b). Based on a bleaching index scaled from 0 to 250 (with 0 as no bleaching and 250 as complete bleaching), Pandolfi *et al.* (2011) report that *Acropora* bleached heavily in Kenya and moderately in Australia in 1998, with scores of 225 and 120, respectively. *Acropora* had a moderate percentage of bleaching on Howland and Baker islands in the U.S. Pacific in early 2010, with 28.7 percent bleached on Baker and 47.7 percent on Howland. *Acropora* was the fifth most-bleached genus out of 14 genera, and was 60 percent as bleached as the most bleached genus (Vargas-Angel *et al.*, 2011).

During a mass-bleaching event in Western Australia in 2010–2011, *Acropora* had the highest mortality with 100 percent mortality of colonies larger than 10 cm diameter in size, and *Montipora* the second highest mortality, while massive and encrusting corals, such as *Porites* and faviids, had much higher survival rates. Colonies less than 10 cm diameter were not killed (Depczynski *et al.*, 2012). *Acropora* in the turbid waters off Okinawa, Japan, experienced sharp drops in populations following the 1998 and 2010 mass bleaching episodes (Hongo and Yamano, 2013). Suthacheep *et al.* (2013) report that all colonies of one species of *Acropora* were completely bleached at Laem Set at Samui Island in the western Gulf of Thailand in 1998 and 80 percent of the colonies of the other reef-building coral species were as well. In 2010, 80 percent colonies of one species were completely bleached and all colonies of the other species were partly bleached. After the 1998 bleaching event, 72 percent of colonies had complete mortality, and after the 2010 event, all bleached colonies had complete mortality.

Bleaching does not always result in mortality, thus it is important to consider bleaching-induced mortality and bleaching rates from a single event, as well as the recovery of a population over time to a bleaching event. In Kenya

in 1998, mortality in *Acropora* was sixth highest of the 18 genera, and 55 percent of the genus with the most mortality (McClanahan, 2004). Three species of *Acropora* were long-term winners following mass bleaching events in Japan (decreasing from 3.4 percent cover to 0 percent then increasing to 3.5 percent; decreasing from 0.2 percent to 0 percent and then increasing to 3.2 percent; decreasing from 1.2 percent cover to 0 percent and then increasing to 0.7 percent), and one species was neither a winner or a loser (van Woesik *et al.*, 2011). Bridge *et al.* (2013a) report that *Acropora* mortality after bleaching was higher than for all corals as a whole. Total coral mortality at 0 to 2 m depth was 70 percent, while it was 90 percent for *Acropora*, and at 3 to 4 m depth it was 20 percent for all corals but 60 percent for *Acropora* (Bridge *et al.*, 2013a).

Species or genera that readily bleach but recover quickly are relatively resilient to warming-induced bleaching. For example, the genus *Acropora* received a +1 resilience score based on trait and process scores assigned to the genus (van Woesik *et al.*, 2012). Traits and processes were chosen which were thought to confer resilience to climate change. Resilience scores of 16 Indo-Pacific genera that were evaluated varied between +7 and -5. Scores below 0 were correlated with a high extinction probability (van Woesik *et al.*, 2012). McClanahan *et al.* (2007a) calculated a relative extinction risk score based on bleaching for genera of corals in the western Indian Ocean. The index of extinction risk was proportional to the degree of bleaching and inversely proportional to the abundance and number of reefs on which a taxon was found. The index of extinction risk for *Acropora* was the ninth lowest out of 47 genera, with a score of 0.11 based on a scale of 0 to 1, with 1 being the score of the highest extinction risk (McClanahan *et al.*, 2007a).

Diseases have been reported to be more common in *Acropora* than in other corals in some areas of the Indo-Pacific, such as the Northwest Hawaiian Islands (Aeby, 2006) and American Samoa (Fenner *et al.*, 2008). However, in the Philippines, *Porites* was the dominant host with almost all disease observed in that genus, and only rarely observed on *Acropora* (Raymundo *et al.*, 2005). In New Caledonia, *Turbinaria* had the highest disease prevalence of any genus with 2.5% infected, while *Acropora* was tied with *Montipora* for the least disease among the 12 most common genera affected, with less than 0.1% infected (Tribollet *et al.*, 2011). On the Great

Barrier Reef, Pocilloporidae and Acroporidae have the highest prevalence of families, and diseases have been recorded on at least 23 species of *Acropora* (Willis *et al.*, 2004). Black band disease on the Great Barrier Reef is concentrated in staghorn *Acropora* species with 76 diseased colonies counted in one study, and *Acropora* species with other colony morphologies (tables, bushy, corymbose, digitate, bottlebrush) had far fewer diseased colonies (Page and Willis, 2006). In American Samoa, French Frigate Shoals (Hawaii) and Johnston Atoll, two species of table *Acropora* (*A. hyacinthus* and *A. cytherea*) had larger numbers of colonies (13 each) with growth anomalies in transects than any of 10 other taxa, and much higher than one other table coral (*A. clathrata*, with one; Work *et al.*, 2008). In Indonesia, bushy *Acropora* had the highest prevalence (8%) of disease of any taxon (out of 35 taxa), while corymbose *Acropora* was the eighth highest taxon and second highest *Acropora* group with 0.5 percent disease, and all other *Acropora* groups (tabulate, bottlebrush, digitate, and staghorn) had 0 percent disease (Haapkyla *et al.*, 2007).

Ocean acidification can have a variety of effects on Indo-Pacific *Acropora* species. While increased CO<sub>2</sub> does not appear to affect the survival of unidentified *Acropora* larvae, postsettlement skeletal growth of the polyps of unidentified *Acropora* species (Suwa *et al.*, 2010) and *A. digitifera* (Inoue *et al.*, 2011) are impaired. In addition, increased CO<sub>2</sub> impairs the rate of zooxanthellae acquisition in the polyps of *A. digitifera* (Inoue *et al.*, 2011) and *A. millepora* (Kaniewska *et al.*, 2012). In Caribbean *Acropora* species, fertilization and settlement are impaired by increased CO<sub>2</sub> (Albright *et al.*, 2010). Elevated CO<sub>2</sub> also induces bleaching in *Acropora*, even more so than temperature increases (Anthony *et al.*, 2008). Carbon dioxide enrichment to 600 to 790 ppm enhanced maximum photosynthetic rates in *A. formosa* (Crawley *et al.*, 2010), but elevated CO<sub>2</sub> levels had no effect on photosynthesis or respiration in *A. eurystoma* (Schneider and Erez, 2006). A study of the effects of near-term ocean acidification and elevated seawater temperature on the physiology of *A. aspera* suggested that gene expression of key metabolic proteins is impacted by the synergistic effects of near term ocean acidification (*i.e.*, the conditions expected to result from 50–90 ppm CO<sub>2</sub> above current atmospheric levels) and ocean warming (Ogawa *et al.*, 2013a). Physical factors may moderate impacts

of acidification, as shown by a study of *A. hyacinthus*, which found that natural daily oscillations in CO<sub>2</sub> may reduce the locally negative effects of increasing ocean acidification (Comeau *et al.*, 2014). Moderate increases in CO<sub>2</sub> may enhance *Acropora* growth and calcification rates in some species, however, at higher CO<sub>2</sub> levels, growth and calcification rates drop to zero. More consistently across species, elevated CO<sub>2</sub> tends to decrease *Acropora* growth and calcification rates (Anthony *et al.*, 2008; Chauvin *et al.*, 2011; Purkis *et al.*, 2011; Schneider and Erez, 2006; Suggett *et al.*, 2013). *Acropora* species appear to be more susceptible to acidification than most other genera, as demonstrated by the lack of *Acropora* species in coral communities existing in naturally low pH waters (Fabricius *et al.*, 2011).

With regard to predation, De'ath and Moran (1998) reported that *Acropora* was the most preferred prey of crown-of-thorns starfish out of the 10 most common genera on 15 reefs in the Great Barrier Reef (preferred 14:1 over *Porites*, the least preferred genus). Pratchett (2001) reported that in a choice experiment, crown-of-thorns starfish always ate *Acropora* colonies before eating colonies of other genera. This was true of all four of the *Acropora* species tested. When a crown-of-thorns starfish has finished eating preferred species, it moves to eating less preferred species, and thus in an outbreak, almost all species may be eaten (Pratchett *et al.*, 2001). The snail *Drupella rugosa* preferred to eat *Acropora pruinosa* over *Montipora informis*, one agaricid and four faviid corals in laboratory tests in Hong Kong (Morton *et al.*, 2002).

The public comments did not provide any supplemental information on genus-level threat susceptibilities for Indo-Pacific *Acropora*. We gathered the supplemental information above, which provides genus-level information on threat susceptibilities of Indo-Pacific *Acropora* for ocean warming, disease, ocean acidification, and predation. We did not gather any supplemental information on the other threats (*i.e.*, sedimentation, nutrients, trophic effects of fishing, sea-level rise, or collection and trade).

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we make the following inferences regarding the susceptibilities of an unstudied *Acropora* species to ocean warming, disease, ocean acidification, predation, sedimentation, nutrients, trophic effects of fishing, sea-level rise, and collection

and trade. Nearly all the studies cited on thermal stress in *Acropora* report high levels of bleaching in response to warming events. Thus, it is possible to predict that an unstudied *Acropora* species is likely to be highly susceptible to warming-induced bleaching, as long as some considerations are kept in mind: (1) Despite high overall susceptibility within the genus to warming-induced bleaching, there can be high variability between species and habitats (Done *et al.*, 2003b); (2) colonies that bleach do not necessarily die (in general, *Acropora* species have higher post-bleaching mortality than corals as a whole, but there is high variability in response throughout the genus); (3) recovery from bleaching provides the mechanism for acclimatization; and (4) while most *Acropora* species readily bleach in response to warming events, most also have the capacity to reestablish local populations relatively quickly through their rapid growth and asexual reproduction capacity.

The studies cited above suggest that diseases are generally more common in *Acropora* than other coral genera, although there are numerous documented exceptions, depending on location. These studies also demonstrate high variability in disease susceptibility across *Acropora* species, depending on growth form, with wide divergence of disease susceptibilities among colony morphological groups under the same conditions. Thus, it is possible to predict that an unstudied *Acropora* species is likely to have some susceptibility to disease.

The studies cited above on ocean acidification in *Acropora* report impacts on skeletal growth rates. Thus, it is possible to predict that an unstudied *Acropora* species is likely to have some susceptibility to ocean acidification in terms of impacts on skeletal growth. The studies cited above on predation in *Acropora* report that predators such as crown-of-thorns starfish and *Drupella* snails prefer to eat *Acropora* over other genera. Thus, it is possible to predict that an unstudied *Acropora* species is likely to have some susceptibility to predation. Most studies summarized in the SRR on the effects of land-based sources of pollution suggest that an unstudied *Acropora* species is likely to have some susceptibility to sedimentation and nutrient enrichment.

The SRR rated the trophic effects of fishing as “medium” importance, and it was the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral

reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Accordingly, an unstudied *Acropora* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sea-level rise as “low-medium” importance to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may provide new coral habitats by submergence of hard substrates; however sea-level rise is also likely to increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, most likely to sediment-tolerant assemblages and slower-growing species. Because *Acropora* are not generally sediment-tolerant and are faster growing species, an unstudied *Acropora* species is likely to have some susceptibility to sea-level rise.

The SRR rated ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall, and this threat was addressed at both the genus and species levels in the SRR. Because *Acropora* species are some of the most popular coral species to collect and trade, an unstudied *Acropora* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Acropora* species is likely to be highly susceptible to ocean warming and to have some susceptibility to disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade.

### *Acropora aculeus*

#### Introduction

The SRR and SIR provided the following information on *A. aculeus*' morphology and taxonomy. Morphology was described as small bushy colonies with flat tops, and taxonomy was described as having no taxonomic issues but being similar in appearance to *A. latistella*.

The public comments and information we gathered provided information on the morphology or taxonomy of *A. aculeus*. One public comment stated that specimens collected in the Mariana Islands and identified by coral expert Richard H. Randall as *A. aculeus* appear to be different than colonies described as *A. aculeus* in references used in the SRR.

Also, one public comment stated that specimens collected in American Samoa and identified by the American Samoa Department of Marine and Water Resources as *A. jacquelineae* appear to be *A. aculeus*, thereby illustrating the species identification uncertainties associated with this species. In addition, we gathered supplemental information, including Veron (2014), which states that this species is distinctive. Thus, while the public comments and supplemental information provided some information on the taxonomy of *A. aculeus*, we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. aculeus*' distribution, habitat, and depth range: *Acropora aculeus* is distributed from East Africa to the Pitcairn Islands in the eastern Pacific. The SRR and SIR reported the species as having the 15th largest range of 114 *Acropora* species in a large study. Its predominant habitat is shallow lagoons, and it is also found in other habitats protected from direct wave action on back-reefs and reef slopes, and its depth range is low tide to at least 20 m.

The public comments did not provide any new or supplemental information on *A. aculeus*' distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 68 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 16. Wallace (1999b) reports its occurrence in 24 of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. aculeus* at over 100 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. aculeus*' habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *A. aculeus*' abundance. *Acropora aculeus* has been reported as generally common and locally abundant, especially in the central Indo-Pacific, and that it is particularly abundant in shallow lagoons and common in most habitats where it is protected from direct wave action.

The public comments did not provide any new or supplemental information on *A. aculeus*' abundance. We gathered supplemental information, including

Richards (2009) and Richards *et al.* (2013b), which concluded that this species is globally widespread, locally widespread, and locally common. Based on these results, the authors concluded that *A. aculeus* is among the most abundant *Acropora* species, and also among those *Acropora* species that are most likely to persist in the future. They placed 12 species in this category out of 85 species of *Acropora*. Veron (2014) reports that *A. aculeus* occupied 32.1 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.55 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was described as "usually common in the central Indo-Pacific, uncommon elsewhere." Veron did not infer abundance trend results from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. aculeus*, the overall decline in abundance ("Percent Population Reduction") was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparisons subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred and are occurring from a combination of global and local threats. Given that *A. aculeus* occurs in many areas affected by these broad changes, and that it is likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. aculeus*' life history. *Acropora aculeus* is a hermaphroditic spawner that is a participant in mass broadcast spawning in some localities. The public comments and information we gathered provided no additional biological information.

#### Susceptibility to Threats

To describe *A. aculeus*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. aculeus*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. aculeus*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, acidification, trophic effects of fishing, nutrient over-enrichment, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments provided some supplemental information on *A. aculeus*' threat susceptibilities. One comment stated that *A. aculeus* is more susceptible to predation than indicated in the proposed rule because of the overlap in the depth ranges of this species with crown of thorns starfish. In addition, we gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora aculeus* has been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Done *et al.* (2003b) report 20 percent of *A. aculeus* colonies were affected by bleaching on the GBR in 2002, and the species ranked 31st in proportion of coral colonies on the GBR that were bleached and killed out of 52 studied *Acropora* species. That is, 30 of the 52 species bleached more than *A. aculeus*, and 21 bleached less. Bonin (2012) reported that *A. aculeus* had a "high" susceptibility to bleaching in Kimbe Bay, Papua New Guinea on a scale of "severe," "high," "moderate," and "lowest." *Acropora aculeus* was fourth highest out of 16 species, with 50 percent of colonies either severely bleached or dead. The most severely affected species had 74 percent of colonies either severely bleached or dead (Bonin, 2012).

*Acropora aculeus* has been rated as moderately or highly susceptible to disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Page and Willis (2007) reported that Skeletal Eroding Band has been found in *A. aculeus*. Skeletal Eroding Band is the most prevalent disease on the Great Barrier Reef. They also reported that corymbose *Acropora* had moderate susceptibility to Skeletal Eroding Band in the Great Barrier Reef, with a prevalence of 2.4 percent (Page and Willis, 2007). No other species-specific information is available for the susceptibility of *A. aculeus* to any other threat.

Based on information from other *Acropora* species provided in the genus description above, *A. aculeus* may be susceptible to the effects of ocean acidification on skeletal growth. Genus-level information also suggests that *A. aculeus* is susceptible to trophic effects of fishing, sedimentation, nutrients, predation, sea-level rise, and collection and trade. Thus, based on the available species-specific and genus information summarized above, *A. aculeus* is likely highly susceptible to ocean warming, and also likely has some susceptibilities to disease, acidification, trophic effects of fishing, sedimentation, nutrients, predation, sea-level rise, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. aculeus* to the threats.

#### Regulatory Mechanisms

In the proposed rule we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. aculeus*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *A. aculeus* occurs in 68 Indo-Pacific ecoregions that encompass 39 countries' EEZs. The 39 countries are Australia, Bangladesh, Brunei, China, Comoros Islands, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (including Andaman and Nicobar Islands), Indonesia, Japan, Kenya, Kiribati, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Mozambique, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Seychelles, Solomon Islands, South Africa, Sri Lanka, Taiwan, Tanzania, Thailand, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory and Pitcairn Islands), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, and

Vietnam. The regulatory mechanisms relevant to *A. aculeus*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (28 percent with 8 percent limited in scope), coral collection (56 percent with 31 percent limited in scope), pollution control (38 percent with 10 percent limited in scope), fishing regulations on reefs (95 percent with 26 percent limited in scope), and managing areas for protection and conservation (97 percent with 8 percent limited in scope). The most common regulatory mechanisms in place for *A. aculeus* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat common for the species, but 31 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *A. aculeus*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. aculeus*. It listed factors that reduce *A. aculeus*' threat of extinction including its geographic range, depth range, abundance, and variable habitats.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. aculeus*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section

above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its predominant habitat is shallow lagoons, and it is found in other habitats protected from direct wave action on back-reefs and reef slopes. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. aculeus* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. aculeus* from threatened to not warranted. We made this determination based on a more species-specific and holistic

assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. aculeus*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora aculeus*' distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future);

(2) *Acropora aculeus*' total absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and

worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. aculeus* is not warranted for listing at this time under any of the listing factors.

#### *Acropora acuminata*

##### Introduction

The SRR and SIR provided the following information on *A. acuminata*'s morphology and taxonomy. Morphology was described as typically forming a tabular base of fused horizontal branches that turn upward and taper to points, and the taxonomy was described as having no taxonomic issues, but colonies turn black when dried.

The public comments and information we gathered provided information on the morphology or taxonomy of *A. acuminata*. One public comment letter stated that specimens of *A. acuminata* in the Mariana Islands may be a different species or a distinct sub-species, based on colony morphology. We gathered supplemental information, including Veron (2014), which states that this species is distinctive. While the public comments and supplemental information provided some information on the morphology and taxonomy of *A. acuminata*, it is sufficiently distinctive to be identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. acuminata*'s distribution, habitat, and depth range. *Acropora acuminata*'s distribution is from the Red Sea to the Pitcairn Islands in the eastern Pacific, covering 110 million km<sup>2</sup>, the 5th largest range of 114 *Acropora* species in a large study. In general, its habitat is upper reef slopes and mid-slope terraces and shelves in turbid or clear water at 15–20 m of depth. In Guam, its habitat is deeper reef flat areas and channel slopes.

The public comments and information we gathered provided information on the distribution and habitat of *A. acuminata*. One public comment letter stated that *A. acuminata* in the Mariana Islands appears to be restricted to reef flats and upper reef slopes in protected to semi-protected areas. Thus, based on all the available information, *A. acuminata*'s habitat can be summarized as follows: Its predominant habitat is upper reef slopes and mid-slope terraces and shelves in turbid or clear water, and it also occurs in back-reef habitats including reef flats and channels. Its depth range is approximately two to 20 m depth. We gathered supplemental information, including Veron (2014), which reports that *A. acuminata* is confirmed in 60 of his 133 Indo-Pacific ecoregions and is strongly predicted to be found in an additional 12. Wallace (1999b) reports its occurrence in 23 of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions.

##### Demographic Information

The SRR and SIR provided the following information on *A. acuminata*'s abundance. *Acropora acuminata* has been reported to occasionally live in extensive clumps with dimensions of several meters, and it can be very common in the center of its range (e.g., Indonesia), but it can be uncommon in the outer parts of its range. The public comments and information we gathered provided information on the abundance of *A. acuminata*. A public comment letter stated that *A. acuminata* in the Mariana Islands is uncommon to rare. We gathered supplemental information, including Richards (2009) and Richards *et al.* (2013b), which conclude from their data that this species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of persistence. They placed 39 species in this category out of 85 species of *Acropora*. Veron (2014) reports that *A. acuminata* occupied 4.7 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.21 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "sometimes common." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron

(2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. acuminata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. acuminata* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *A. acuminata*'s life history. Like most of its congeners, *A. acuminata* is a broadcast spawner. However, some degree of reproductive isolation probably occurs in some locations because the species does not spawn synchronously with the majority of its congeners. The public comments and information we gathered provided no additional biological information.

##### Susceptibility to Threats

To describe *A. acuminata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also stated that *Acropora acuminata* is the only *Acropora* known to not be preferred as prey by the crown-of-thorns starfish, thus susceptibility to predation appears to be low. The SRR and SIR did not

provide any other species-specific information on the effects of these threats on *A. acuminata*. The threat susceptibility and exposure information from the SRR and SIR was interpreted in the proposed rule for *A. acuminata*'s vulnerabilities to threats: High vulnerability to ocean warming; moderate vulnerability to disease, acidification, trophic effects of reef fishing, and nutrient over-enrichment; and low vulnerability to sedimentation, sea-level rise, predation, and collection and trade.

Public comments did not provide any information on *A. acuminata*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora acuminata* has been rated as moderately or highly susceptible to bleaching and coral disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on information from other *Acropora* species provided in the genus description above, *A. acuminata* likely has high susceptibility ocean warming, and also has some susceptibilities to coral disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. Thus, based on the available species-specific and genus information summarized above, *A. acuminata* is likely highly susceptible to ocean warming, likely has some susceptibilities to disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, and collection and trade, and also has low susceptibility to predation.

#### Regulatory Mechanisms

In the proposed rule we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. acuminata*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *A. acuminata* occurs in 60 Indo-Pacific ecoregions that encompass 42 countries' EEZs. The 42 countries are Australia, Brunei, China, Comoros Islands, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Japan, Jordan, Kiribati, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, Nauru, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan,

Taiwan, Thailand, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory, Pitcairn Islands), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms available to *A. acuminata*, described first as a percentage of the above countries that utilize them to any degree, and second as the percentages of those countries whose regulatory mechanisms may be limited in scope, are general coral protection (29 percent with 7 percent limited in scope), coral collection (60 percent with 29 percent limited in scope), pollution control (45 percent with 7 percent limited in scope), fishing regulations on reefs (90 percent with 21 percent limited in scope), and managing areas for protection and conservation (93 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. acuminata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. acuminata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. acuminata*. It listed factors that reduce the threat of extinction including the very wide geographic range, the broad depth range, the fact that it is often common and sometimes abundant, and the somewhat broad range of suitable habitats for *A. acuminata*.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed

to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. acuminata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from 15 to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes multiple habitat types on both the reef slope and back reef. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. In addition, turbidity can mitigate against the effects of high irradiance by blocking it from the water column in turbid environments. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and ocean acidification across the species' range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula, *A. acuminata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide

abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. acuminata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. acuminata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora acuminata*'s distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species' range. As explained in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species' range within the foreseeable future;

(2) *Acropora acuminata*'s total absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all the individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. acuminata* is not warranted for listing at this time under any of the listing factors.

#### *Acropora aspera*

##### Introduction

The SRR and SIR provided the following information on *A. aspera*'s morphology and taxonomy. The morphology was described as arborescent or bushy clumps which may have largely vertical branches, and the taxonomy was described as having no taxonomic issues.

The public comments did not provide supplemental information on morphology. We gathered supplemental information, including van Oppen *et al.* (2001), which found that *A. aspera* is the only genetically distinct member of the *A. aspera* group of *Acropora* species, a group of morphologically similar species that hybridize at least occasionally. Other supplemental information we gathered was Veron (2014), which states that *A. aspera* is distinctive, thus we conclude it is sufficiently distinctive to be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. aspera*'s distribution, habitat, and depth range. *Acropora aspera* is distributed from the Red Sea to the Samoan Islands. The species has a relatively broad range, the 46th largest range of 114 *Acropora*

species in a large study. It occurs in a broad range of habitats and its depth range as low tide to at least 10 m.

The public comments did not provide supplemental information on *A. aspera*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 68 of his 133 Indo-Pacific ecoregions, and is strongly predicted to be found in an additional 17. Wallace (1999b) reports its occurrence in 21 of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions, and Richards (2009) calculated the geographic range of *A. aspera* at 70 million km<sup>2</sup>. Wallace (1999b) describes its habitat as "intertidal/shallow subtidal," and in much of its range the species is confined to reef flats. Thus, based on all the available information, *A. aspera*'s habitat can be summarized as follows: The species occurs in a broad range of habitats on the reef slope and back-reef, including but not limited to lower reef crests, upper reef slopes, reef flats, and lagoons. Its depth range is approximately low tide to 20 m depth.

##### Demographic Information

The SRR and SIR provided the following information on *A. aspera*'s abundance. *Acropora aspera* has been reported as sometimes locally common and it can occasionally live in extensive clumps with dimensions of several meters.

The public comments and information we gathered provided information on the abundance of *A. aspera*. One public comment letter stated that *A. aspera* is relatively limited in abundance in Guam compared to co-occurring arborescent species such as *Acropora pulchra* and *Acropora muricata*. We gathered supplemental information, including Veron (2014), which reports that *A. aspera* occupied 7.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.76 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was described as "sometimes common." Veron did not infer trends in abundance from these data. *Acropora aspera* is a reef flat species, and reef flats have a larger global area than reef slopes (Vecsei, 2004). This information is relevant because most coral abundance surveys are carried out only on reef slopes, and thus may significantly underestimate the abundance of species such as *A. aspera* that are more common

on reef-flats than reef slopes. In American Samoa, *A. aspera* forms clumps on reef flats many meters across, as much as about 100 m in some places (D. Fenner, personal comm.). Richards (2009) and Richards *et al.* (2013b) conclude from their data that this species is globally widespread, locally restricted, and locally common, and thus in one of the categories of highest abundance with the predicted consequence of persistence. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. aspera*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences of species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. aspera* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. aspera*’s life history. *Acropora aspera* is a hermaphroditic spawner. While it is a participant in mass broadcast spawning in some localities, asynchronous gamete development on the Great Barrier Reef and New Caledonia may provide a degree of reproductive isolation, although *A. aspera* has been shown to hybridize with other acroporids. Gamete development in *A. aspera* may be

aborted in years with storm impacts. Asexual reproduction can account for the majority of *A. aspera* population structure in certain areas and can lead to local dominance.

The public comments provided no supplemental biological information. We gathered the following information. In a study of biological traits of coral species, Darling *et al.* (2012) found that all of over 30 *Acropora* species studied were classified as “competitive” species which were considered to be less tolerant of environmental stress and disturbance than those species that were classified as “stress-tolerant,” “generalist,” or “weedy”, because of documented shifts in coral communities from “competitive” to the other categories. *Acropora aspera* was one of the *Acropora* species studied, and was classified as “competitive” as were all other *Acropora* species.

#### Susceptibility to Threats

To describe *A. aspera*’s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. aspera*. The threat exposure and susceptibility information from the SRR and SIR was interpreted in the proposed rule for *A. aspera*’s vulnerabilities to threats as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide supplemental information on *A. aspera*’s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species’ threat susceptibilities. *Acropora aspera* was rated as moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Done *et al.* (2003b) reported that 33 percent of *A. aspera*’s colonies on the GBR were affected by bleaching in 2002, and the species ranked 9th in proportion of coral colonies that were bleached out of 52 studied *Acropora* species. That is, eight of the 52 species bleached more than *A. aspera*, and 43 bleached less.

*Acropora aspera* experiences sub-acute black-band disease (UNEP, 2010), as well as ciliate infections (Antonius and Lipscomb, 2000). Page and Willis (2007) reported that Skeletal Eroding

Band has been found in *A. aspera*. They also reported that bushy *Acropora* had high susceptibility to Skeletal Eroding Band on the GBR, with a prevalence of 3.1 percent. Skeletal Eroding Band is the most prevalent disease on the GBR. A study of the effects of near-term ocean acidification and elevated seawater temperature on the physiology of *A. aspera* suggested that gene expression of key metabolic proteins is impacted by the synergistic effects of near term ocean acidification (*i.e.*, the conditions expected to result from 50 to 90 ppm CO<sub>2</sub> above current atmospheric levels) and ocean warming (Ogawa *et al.*, 2013b). *Acropora aspera* is a preferred prey of crown-of-thorns seastar (Sonoda and Paul, 1993). With regard to sedimentation, *A. aspera* was found to be relatively tolerant of silty, turbid water in the South China Sea (Latypov and Dautova, 2005). No other species-specific information is available for the susceptibility of *A. aspera* to any other threat.

Based on the available genus-level and species-specific information, *A. aspera* is likely highly susceptible to ocean warming, and it also likely has some susceptibilities to disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. aspera* to the threats.

#### Regulatory Mechanisms

In the proposed rule we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. aspera*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *Acropora aspera* occurs in 68 Indo-Pacific ecoregions that encompass 44 countries’ EEZs. The 44 countries are Australia (including Cocos-Keeling Islands), Bahrain, Brunei, Cambodia, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (including Andaman and Nicobar Islands), Indonesia, Iran, Japan, Kiribati, Kuwait, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, New Zealand (Tokelau), Niue, Oman, Palau, Papua New Guinea, Philippines, Qatar, Samoa, Saudi Arabia, Seychelles, Singapore, Solomon Islands, Sri Lanka, Taiwan, Thailand, Timor-Leste, Tonga, Tuvalu, United Arab Emirates, United Kingdom (British Indian Ocean Territory), United

States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms available to *A. aspera*, described first as a percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms are limited in scope, are as follows: General coral protection (32 percent with 9 percent limited in scope), coral collection (52 percent with 25 percent limited in scope), pollution control (43 percent with 7 percent limited in scope), fishing regulations on reefs (91 percent with 23 percent limited in scope), and managing areas for protection and conservation (89 percent with 9 percent limited in scope). The most common regulatory mechanisms in place for *A. aspera* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 25 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. aspera*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. aspera*. It listed factors that reduce the threat of extinction including the wide geographic range, the fact that it is often common and sometimes abundant, and the somewhat broad range of suitable habitats for *A. aspera*.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. aspera*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to at least 10 meters. Assuming that the species' depth distribution is limited to 10 meters, this exacerbates vulnerability to extinction over the foreseeable future because shallow areas are more likely to be affected by warming-induced bleaching and disease than deeper areas. Its habitat includes lower reef crests, upper reef slopes, reef flats, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. aspera* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); narrow overall distribution (based on moderate geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. aspera* from threatened to not warranted. We made

this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. aspera*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora aspera*'s distribution is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora aspera*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species'

exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. aculeus* is not warranted for listing at this time under any of the listing factors.

### *Acropora dendrum*

#### Introduction

The SRR and SIR provided the following information on *A. dendrum*'s morphology and taxonomy. The morphology was described as plates 0.5 to 1 m diameter, with widely spaced vertical branchlets, and taxonomy was described as having no taxonomic issues. However, *A. dendrum* is "poorly characterized and may indeed be a 'phantom' species, being made up from specimens that cannot be allocated to other species." However, the BRT treats it as a nominal species. They stated that it is most similar to *Heteropora appressa* and *A. microclados*.

The public comments did not provide supplemental information on morphology or taxonomy. We gathered supplemental information, which confirmed that while there is some taxonomic uncertainty for *A. dendrum*, it is recognized as valid by experts (Veron, 2000; Veron, 2014; Wallace, 1999b). Veron (2014) states that *A. dendrum* is distinctive, thus we conclude it is sufficiently distinctive to be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. dendrum*'s distribution, habitat, and depth range. *Acropora dendrum* is distributed from the north-central Indian Ocean to Fiji, and from Japan to the Great Barrier Reef. The species' predominant habitat is upper reef slopes and mid-slope terraces, and its depth range is 5 to 20 m. Upper reef slopes and mid-slope terraces extend seaward from the reef crest toward the open ocean, forming one of the most common and widespread coral reef habitats. They vary in gradient from gentle to steep, and include a great deal of physical

complexity, including ridges, furrows, walls, caves, and other structures, collectively providing highly diverse coral habitats.

The public comments did not provide supplemental information on *A. dendrum*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 32 of his 133 Indo-Pacific ecoregions, and is strongly predicted to be found in an additional 20. Wallace (1999b) reports its occurrence in nine of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions, and Richards (2009) reported the species as having the 48th smallest range of 114 *Acropora* species in a large study and calculated the geographic range at over 20 million km<sup>2</sup>. *Acropora dendrum* occurs on exposed reef fronts where *Acropora* diversity is high (Veron and Wallace, 1984). The public comments and information we gathered provided nothing additional on *A. dendrum*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *A. dendrum*'s abundance. *Acropora dendrum* has been reported as uncommon or rare.

The public comments did not provide supplemental information on *A. dendrum*'s abundance. We gathered supplemental information, which indicates that there are no locations recorded where *A. dendrum* is common or even more abundant than a rare species (Wallace, 1999b). Veron (2014) provides a much more detailed range map for this species than the maps used in the SRR, and reports that *A. dendrum* occupied 2.0 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.11 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "rare." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. dendrum*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population

Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences of species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. dendrum* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. dendrum*'s life history. Like most of its congeners, *A. dendrum* is a hermaphroditic spawner (Mezaki *et al.*, 2007; Wallace, 1985) with lecithotrophic (yolk-sac) larvae (Baird *et al.*, 2009). The public comments and information we gathered provided no supplemental biological information.

#### Susceptibility to Threats

To describe *A. dendrum*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. dendrum*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. dendrum*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide supplemental information on *A. dendrum*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora dendrum* has

been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on information from other *Acropora* species provided in the genus description above, *A. dendrum* is likely to be highly susceptible to ocean warming, and also has some susceptibilities to disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. dendrum* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. dendrum*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. *Acropora dendrum* has confirmed records of occurrence in 32 Indo-Pacific ecoregions that encompass 14 countries' EEZs. The 14 countries are Australia, Brunei, China, France (French Pacific Island Territories), Indonesia, Japan, Malaysia, Myanmar, Papua New Guinea, Philippines, Solomon Islands, Thailand, Vanuatu, and Vietnam. The regulatory mechanisms available to *A. dendrum*, described first as a percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms are limited in scope, are as follows: General coral protection (36 percent with seven percent limited in scope), coral collection (57 percent with 29 percent limited in scope), pollution control (43 percent with 21 percent limited in scope), fishing regulations on reefs (100 percent with 21 percent limited in scope), and managing areas for protection and conservation (93 percent with none limited in scope). The most common regulatory mechanisms in place for *A. dendrum* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 29 percent of those laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. dendrum*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species'

vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. dendrum*. It listed factors that reduce the threat of extinction, including the fairly wide geographic range, the depth range, and the somewhat broad range of suitable habitats.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. dendrum*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic range extends from western Malaysia to Vanuatu, and southern Japan to the GBR. On one hand, this moderates vulnerability to extinction because the high latitude areas in the northern and southern portions of its range are projected to have less than average warming over the foreseeable future, thus populations in these areas will be less exposed to severe warming conditions. On the other hand, the species' geographic distribution exacerbates vulnerability to extinction because much of it lies within the western equatorial Pacific, an area projected to have the highest seawater temperatures in the foreseeable future. Its depth range is from 5 to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes and mid-slope terraces. This moderates vulnerability to extinction over the

foreseeable future because upper reef slopes and mid-slope terraces are physically diverse and widespread, thus the species occurs in reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. dendrum* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); rare generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. dendrum* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. dendrum*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora dendrum*'s distribution is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to

any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora dendrum*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) As with other *Acropora* species, it is a broadcast spawner and fast grower, enhancing recovery potential from mortality events.

Notwithstanding projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. dendrum* is not warranted for listing at this time under any of the listing factors.

#### *Acropora donei*

##### Introduction

The SRR and SIR provided the following information on *A. donei*'s morphology and taxonomy. Morphology was described as table-like, up to 2 m diameter, with branchlets that are horizontal near the edge but upturned in the middle, and taxonomy was described as having no taxonomic issues, but being similar in appearance to *A. yongei*.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, which indicated that there is some taxonomic uncertainty with this species, but that it is recognized as valid by experts (Fukami *et al.*, 2004; Veron, 2000). Veron (2014) states that *A. donei* is distinctive, thus we conclude it is sufficiently distinctive to be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. donei*'s distribution, habitat, and depth range. *Acropora donei* is distributed from the northern Indian Ocean to the central Indo-Pacific, and from Australia to Japan. They reported that it had the 44th largest range of 114 *Acropora* species examined. The species' habitat is upper reef slopes and mid-slope terraces. It may be restricted habitats where *Acropora* diversity is high, but this includes a large proportion of the Indo-Pacific's reef slopes. Its depth range is 5 to 20 m.

The public comments did not provide any new or supplemental information on *A. donei*'s distribution. We gathered supplemental information, including Veron (2014), which provides an updated, much more detailed range map for this species than the maps used in the SRR. Veron reports that *A. donei* is confirmed in 50 of his 133 Indo-Pacific ecoregions, and is strongly predicted to be found in an additional 17. Wallace (1999b) reports its occurrence in 20 of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions. *Acropora donei* has a relatively broad range overall, estimated at 75 million km<sup>2</sup> (Richards, 2009). The public comments and information we gathered provided nothing additional on *A. donei*'s habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. donei*'s abundance. *Acropora donei* has been reported to be uncommon. Richards (2009) concluded that *A. donei* is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction. The public comments and information we gathered provided information on *A. donei*'s abundance. One public comment stated that a recently published paper (Kayanne *et*

*al.*, 2012) reported that *A. donei* was among the second most abundant group of corals on Okinotorishima, Japan, and was classified as "common" (paper was provided with the comment). We gathered supplemental information, which reports that *A. donei* is a common species on Indonesian reefs and reefs of the South China Sea and Japan (Wallace and Wolstenholme, 1998). Veron (2014) reports that *A. donei* occupied 4.7 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.16 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. donei*, the overall decline in abundance ("Percent Population Reduction") was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event ("Broadcast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. donei* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

### Other Biological Information

The SRR and SIR provided the following information on *A. donei*'s life history. *Acropora donei* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered provided no additional biological information.

### Susceptibility to Threats

To describe *A. donei*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. donei*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. donei*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. donei*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora donei* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on information from other *Acropora* species provided in the genus description above, *A. donei* is likely highly susceptible to ocean warming, and likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. donei* to the threats.

### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. donei*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. donei* occurs in 68 Indo-Pacific ecoregions that encompass 34 countries' EEZs. The 34 countries are Australia,

Brunei, China, Comoros Islands, Djibouti, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Japan, Kiribati, Madagascar, Malaysia, Maldives, Marshall Islands, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Sri Lanka, Taiwan, Thailand, Tonga, Tuvalu, United States (American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms relevant to *A. donei*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (32 percent with 6 percent limited in scope), coral collection (59 percent with 29 percent limited in scope), pollution control (44 percent with 9 percent limited in scope), fishing regulations on reefs (97 percent with 15 percent limited in scope), and managing areas for protection and conservation (94 percent with 3 percent limited in scope). The most common regulatory mechanisms in place for *A. donei* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. donei*.

### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. donei*. It listed factors that reduce the threat of extinction including the moderate geographic and depth ranges.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the

species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. donei*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from five to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes and mid-slope terraces. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

### Listing Determination

In the proposed rule using the determination tool formula, *A. donei* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate

depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. donei* from threatened to not warranted. We made this decision based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. donei*'s spatial structure, demography, threat susceptibilities, and management none of the five ESA factors, alone or in combination, are causing this species to be endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora donei*'s distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future);

(2) *Acropora donei*'s total absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species

possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. donei* is not warranted for listing at this time under any of the listing factors.

#### *Acropora globiceps*

##### Introduction

The SRR and SIR provided the following information on *A. globiceps*' morphology and taxonomy. Morphology was described as digitate and usually small, and taxonomy was described as having no taxonomic issues, but radial corallites were reported similar to *Acropora secale* and *Acropora retusa*. It appears similar to *Acropora gemmifera*, but in strong wave action is similar to *Acropora monticulosa*.

The public comments did not provide any new or supplemental information on morphology and taxonomy. We gathered supplemental information, including Wallace (1999b), which states that *A. globiceps*' branch thickness and colony shape is similar to that of *Acropora humilis*, and its branch shape and radial corallite morphology is similar to that of *Acropora samoensis*. It appears that this species has often been mistaken for *A. humilis* (Fenner, 2014b). Veron (2014) states that *A. globiceps* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. globiceps*' distribution, habitat, and depth range. *Acropora globiceps* is distributed from the oceanic west Pacific to the central Pacific as far east as the Pitcairn Islands. The species has the 27th smallest range of 114 *Acropora* species in a large study. The species occurs on upper reef slopes,

reef flats, and adjacent habitats in depths ranging from 0 to 8 m.

The public comments did not provide any new or supplemental information on *A. globiceps*' distribution. We gathered supplemental information, including Veron (2014), which reports that *A. globiceps* is confirmed in 22 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 16. Wallace (1999b) reports its occurrence in seven of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions. Wallace's (1999b) map shows it from a smaller area than Veron (Veron, 2000; Veron, 2014). Based on the Wallace (1999b) range, *A. globiceps* has a relatively small range, estimated at 5 million km<sup>2</sup> (Richards, 2009). The public comments and information we gathered provided nothing additional on *A. globiceps*' habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. globiceps*' abundance. *Acropora globiceps* has been reported as common (Veron, 2000). The public comments did not provide any new or supplemental information on *A. globiceps*' abundance. We gathered supplemental information, including Veron (2014), which reports that *A. globiceps* occupied 3.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.95 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "sometimes common." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. globiceps*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent (Carpenter *et al.*, 2008). However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences

to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. globiceps* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. globiceps*' life history. *Acropora globiceps* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide additional biological information.

#### Susceptibility to Threats

To describe *A. globiceps*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, and nutrients. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. globiceps*. The exposure and susceptibility threat information from the SRR and SIR was interpreted in the proposed rule for *A. globiceps*' vulnerabilities to threats as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. globiceps*' threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora globiceps* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on information from other *Acropora* species provided in the genus description above, *A. globiceps* is likely highly susceptible to ocean warming, and also likely has some susceptibilities

to disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. globiceps* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. globiceps*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. globiceps* occurs in 22 Indo-Pacific ecoregions that encompass 19 countries' EEZs. The 19 countries are Australia, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Japan, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Solomon Islands, Timor-Leste, Tonga, Tuvalu, United Kingdom (Pitcairn Islands), United States (CNMI, Guam, American Samoa), and Vietnam. The regulatory mechanisms relevant to *A. globiceps*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (32 percent with none limited in scope), coral collection (74 percent with 37 percent limited in scope), pollution control (42 percent with 16 percent limited in scope), fishing regulations on reefs (100 percent with 11 percent limited in scope), and managing areas for protection and conservation (100 percent with 5 percent limited in scope). The most common regulatory mechanisms in place for *A. globiceps* are reef fishing regulations, area management for protection and conservation, and coral collection laws. However, 37 percent of coral collection laws are limited in scope and may not provide substantial protection. Pollution control laws are also somewhat utilized for the species. General coral protection laws are much less common regulatory mechanisms for the management of *A. globiceps*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated

that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. globiceps*, but the narrow depth range also increases the risk of extinction. It listed factors that reduce the threat of extinction including common abundance and persistence in intertidal habitats.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. globiceps*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes the Coral Triangle, but also includes many coral reef ecoregions in the western and central Pacific Ocean, as far east as the Pitcairn Islands. Some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, so portions of the population in these areas will be less exposed to severe conditions. On the other hand, the Coral Triangle area is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. As such, its geographic distribution has the ability to both moderate and exacerbate vulnerability to extinction. Its depth range of zero to 8 meters exacerbates vulnerability to extinction over the foreseeable future because a large proportion of the population is restricted to shallow areas. Shallow reef areas can be physically diverse, but are often subjected to frequent changes in environmental conditions, extremes, high irradiance, and simultaneous effects from multiple stressors, both local and global in nature. Its habitat includes upper reef slopes, reef flats, and adjacent habitats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous

types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. globiceps* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); narrow overall distribution (based on moderate geographic distribution and narrow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we maintain the listing determination for *A. globiceps*. Based on the best available information provided above on *A. globiceps*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora globiceps* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of fishing (A, E), nutrients (A, E), and predation (C). These threats are expected to continue and increase into the future. In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D); and

(2) *Acropora globiceps* occurs primarily in depths of zero to eight meters which can be considered a shallow depth range compared to the overall depth of occurrence for reef building corals in general. Shallow reef areas are often subjected to highly variable environmental conditions, extremes, high irradiance, and simultaneous effects from multiple stressors, both local and global in nature. A limited depth range reduces the absolute area in which the species may occur throughout its geographic range and indicates that a large proportion of the population is likely to

be exposed to threats that are worse in shallow habitats, such as simultaneously elevated irradiance and seawater temperatures, as well as localized impacts.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. globiceps*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. globiceps*' distribution includes the Coral Triangle area, it also includes many ecoregions throughout the central Pacific from Japan down to New Caledonia and as far east as the Pitcairn Islands. This distribution includes some areas within its range that are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, so portions of the population in these areas will be less exposed to severe conditions.

(2) *Acropora globiceps*' absolute abundance is at least tens of millions of colonies which allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. globiceps*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not

believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora horrida*

##### Introduction

The SRR and SIR provided the following information on *A. horrida*'s morphology and taxonomy. Morphology was described as usually open branched, becoming bushy on upper reef slopes and in shallow lagoons. No taxonomic issues were raised, but *A. horrida* was stated to be similar to *Acropora tortuosa*, and *Acropora vaughani*.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which states that *A. horrida* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. horrida*'s distribution, habitat, and depth range. *Acropora horrida* is distributed from the Red Sea to French Polynesia. The species has a very broad range overall, having the 14th largest range of 114 *Acropora* species examined. It is found in numerous reef slope and back-reef habitats with turbid water, including but not limited to, upper reef slopes, mid-slope terraces, lagoons, and adjacent habitats. The SRR described its depth range as 5 to 20 m.

The public comments did not provide any new or supplemental information on *A. horrida*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 61 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 22. Wallace (1999b) reports its occurrence in 24 of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. horrida* at over 100 million km<sup>2</sup>. Wallace (1999b) reports the depths from which *A. horrida* specimens were collected ranged from 17 to 39 m.

##### Demographic Information

The SRR and SIR provided the following information on *A. horrida*'s abundance. *Acropora horrida* has been

reported as usually uncommon. This is a species that is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction. The public comments did not provide any new or supplemental information on *A. horrida*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. horrida* occupied 8.9 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.70 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. horrida*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. horrida* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. horrida*'s life history. *Acropora horrida* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. Mean egg size for *A. horrida* has been recorded as 0.64 mm and mean polyp fecundity has been recorded as 9.0 eggs per polyp. This species did synchronize its spawning with other *Acropora* species on the central GBR during the major multispecies spawning events in early summer 1981–1983.

Public comments provided no additional biological information. We gathered the following supplemental information on the life history of *A. horrida*. Darling *et al.* (2012) found that all of over 30 *Acropora* species studied were classified as "competitive" species which were considered to be less tolerant of environmental stress and disturbance than those species that were classified as "stress-tolerant," "generalist," or "weedy," because of documented shifts in coral communities from "competitive" to the other categories. *Acropora horrida* was one of the *Acropora* species studied.

#### Susceptibility to Threats

To describe *A. horrida*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR also provided the following species-specific information on *A. horrida*'s threats. With regard to ocean warming, *A. horrida* is thought to have been locally extirpated in the Arabian Gulf after the 1996 and 1998 bleaching events, but the species is considered less susceptible to bleaching than other *Acropora* spp. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. horrida*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. horrida*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. lokani*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora horrida* has been rated as moderately or highly

susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Done *et al.* (2003b) reported that 20 percent of *A. horrida* colonies on the Great Barrier Reef were affected by bleaching in 2002, and the species ranked 29th in proportion of coral colonies that were bleached and killed out of 52 studied *Acropora* species. That is, 28 of the 52 species bleached more than *A. horrida*, and 23 bleached less.

No other species-specific information is available for the susceptibility of *A. horrida* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. horrida* may be susceptible to the effects of disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. Thus, based on the available species-specific and genus information summarized above, *A. horrida* is likely highly susceptible to ocean warming, and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, predation, sedimentation, nutrients, sea-level rise, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. horrida* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. horrida*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. horrida* occurs in 61 Indo-Pacific ecoregions that encompass 45 countries' EEZs. The 45 countries are Australia, Bahrain, China, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Iran, Israel, Japan, Jordan, Kenya, Kiribati, Kuwait, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Mozambique, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Qatar, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sudan, Taiwan, Tanzania, Thailand, Tonga, Tuvalu, United Arab Emirates, United Kingdom (British Indian Ocean Territory), United States (American Samoa, PRIAs), Vietnam, and Yemen. The regulatory mechanisms relevant to *A. horrida*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those

countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (24 percent with 2 percent limited in scope), coral collection (58 percent with 24 percent limited in scope), pollution control (44 percent with 7 percent limited in scope), fishing regulations on reefs (87 percent with 24 percent limited in scope), and managing areas for protection and conservation (87 percent with 11 percent limited in scope). The most common regulatory mechanisms in place for *A. horrida* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 24 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. horrida*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. horrida*. It listed factors that reduce the threat of extinction including the very wide geographic range, with large local distributions, and tolerance for turbid water.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. horrida*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral

reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from five to 39 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes numerous reef slope and back-reef habitats with turbid water, including but not limited to, upper reef slopes, mid-slope terraces, lagoons, and adjacent habitats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. In addition, turbidity can mitigate the effects of high irradiance by blocking it from the water column. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. horrida* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. horrida* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment

of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. horrida*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora horrida*'s distribution from the Red Sea across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora horrida*'s total absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species

exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. horrida* is not warranted for listing at this time under any of the listing factors.

### *Acropora jacquelineae*

#### Introduction

The SRR and SIR provided the following information on *A. jacquelineae*'s morphology and taxonomy. The morphology was described as flat plates up to 1 m in diameter. Viewed from above, plates are covered with a mass of fine delicately-curved axial corallites giving an almost moss-like appearance. Evidence from genetics indicates it is not a hybrid, and so the SRR considered it a valid species.

The public comments and information we gathered provided supplemental information on the morphology or taxonomy of *A. jacquelineae*. One public comment stated that specimens collected in American Samoa and identified by the American Samoa Department of Marine and Water Resources as *A. jacquelineae* appear to be *A. aculeus*, thereby illustrating the species identification uncertainties associated with this species. We gathered supplemental information, including Veron (2014), which states that *A. jacquelineae* is distinctive when compared with other species but not on its own. We conclude the species can be identified by experts (Fenner, 2014b). Thus, we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. jacquelineae*'s distribution, habitat, and depth range. *Acropora jacquelineae* is distributed within the Coral Triangle including Papua New Guinea, and is reported from American Samoa. The species has a limited range overall, the 22nd smallest range of 114 *Acropora* species. It is found in numerous subtidal reef slope and back-reef habitats, including but not limited to,

lower reef slopes, walls and ledges, mid-slopes, and upper reef slopes protected from wave action, and its depth range is 10 to 35 m.

The public comments did not provide any new or supplemental information on *A. jacquelineae*'s distribution, habitat, or depth range. We gathered supplemental information on its distribution, including Veron (2014), which reports that *A. jacquelineae* is confirmed in 12 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional five. Wallace (1999b) reports its occurrence in seven of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range of this species at 2 million km<sup>2</sup>, which was 1.8 percent of the size of the largest range for any species.

#### Demographic Information

The SRR and SIR provided the following information on *A. jacquelineae*'s abundance. *Acropora jacquelineae* has been reported as uncommon.

The public comments did not provide any new or supplemental information on *A. jacquelineae*'s abundance. We gathered supplemental information, including Richards (2009) and Richards *et al.* (2013b), which conclude from their data that *A. jacquelineae* is globally restricted, locally restricted, and locally rare, and thus in the rarest category of *Acropora* with the predicted consequence of global extinction. They placed 15 species in this category out of 85 species of *Acropora*. Bonin (2012) reported that *A. jacquelineae* was the 19th most abundant species of *Acropora* in Kimbe Bay, Papua New Guinea, with about 18 percent of the abundance of the most abundant species of *Acropora*. Veron (2014) reports that *A. jacquelineae* occupied 1.6 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.44 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data.

Richards *et al.* (2008) reported that *A. jacquelineae* had the 14th lowest population of the 15 rare *Acropora* species they studied. Richards *et al.* (2008) gave the total world population of this species as 31,599 +/-17,358 colonies, and the effective population size (*i.e.*, a mathematical estimate of the size of the breeding population) as 3,476

colonies. The calculation of the total world population of this species was flawed, since the area of 1 km<sup>2</sup> was given as 1,000 m<sup>2</sup> (Richards *et al.*, 2008: Appendix 1), when it is actually 1,000,000 m<sup>2</sup>. Thus, the correct population estimate is 1,000 times greater than stated, or a total population size of 31,599,000 colonies, and an effective population size of 3,476,000 colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. jacquelineae*, the overall decline in abundance ("Percent Population Reduction") was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. jacquelineae* occurs in many areas affected by these broad changes, and has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. jacquelineae*'s life history. *Acropora jacquelineae* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. jacquelineae*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not

provide any species-specific information on the effects of these threats on *A. jacquelineae*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. jacquelineae*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerability to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. jacquelineae*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora jacquelineae* has been rated as moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). There is no species-specific information for the exposure or susceptibility of *A. jacquelineae* to any threat. Thus, based on the available genus information summarized above, *A. jacquelineae* is likely highly susceptible to ocean warming, and also likely has some susceptibility to disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. jacquelineae* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. jacquelineae*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. jacquelineae* occurs in 12 Indo-Pacific ecoregions that encompass five countries' EEZs. The five countries are Federated States of Micronesia, Indonesia, Papua New Guinea, Solomon Islands, and Timor-Leste. The regulatory mechanisms relevant to *A. jacquelineae*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (20 percent with none limited in scope), coral collection (40 percent with none limited in scope), pollution control (20 percent with 20 percent limited in scope), fishing regulations on reefs (100 percent

with none limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *A. jacquelineae* are reef fishing regulations and area management for protection and conservation. General coral protection, coral collection, and pollution control laws are much less common regulatory mechanisms for the management of *A. jacquelineae*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. jacquelineae*. It listed factors that contribute to the threat of extinction including limited range, small local distribution and small local abundance, as well as the possibility of genetic introgression.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. jacquelineae*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited almost exclusively to the Coral Triangle in the western equatorial Pacific Ocean. Despite the large number of islands and environments that are included in the species range, this range exacerbates vulnerability to extinction over the foreseeable future because it is limited to the area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range of ten to 35 meters

moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes lower reef slopes, walls and ledges, mid-slopes, and upper reef slopes protected from wave action. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its effective population size estimate of approximately 3.5 million colonies, combined with the location of its range, exacerbates vulnerability to extinction because increasingly severe conditions within the limited species range are likely to affect a high proportion of its effective population at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. jacquelineae* was proposed for listing as endangered because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); rare generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. jacquelineae* from endangered to threatened. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including adequate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information provided above on *A. jacquelineae*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora jacquelineae* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of

fishing (A), predation (C), and nutrient enrichment (A, E). These threats are expected to continue and increase into the future. In addition existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D).

(2) *Acropora jacquelineae*'s distribution is constrained mostly to the Coral Triangle and western equatorial Pacific, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Acropora jacquelineae*'s absolute abundance is estimated to be 31 million colonies, however its estimated effective population size is much lower at approximately 3.5 million genetically distinct individuals. Considering the limited range of this species in an area where severe and increasing impacts are predicted, this level of abundance leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. jacquelineae*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. jacquelineae*'s distribution is constrained mostly to the Coral Triangle which increases its extinction risk as described above, its habitat includes sub-tidal walls, ledges on walls, and shallow reef slopes protected from wave action. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in

numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat subsection and Threats Evaluation section. There is no evidence to suggest the species is so spatially fragmented that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species;

(2) *Acropora jacquelineae*'s absolute abundance is tens of millions of colonies and effective population size is still millions of colonies which allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of depensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events, as described in the Corals and Coral Reefs section above.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. jacquelineae*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora listeri*

##### Introduction

The SRR and SIR provided the following information on *A. listeri*'s morphology and taxonomy. Morphology was described as irregular clumps or

plates with thick branches of highly irregular length and shape, and the taxonomy was described as having no taxonomic issues but this species was reported to be similar to *Acropora polystoma* and *Acropora lutkeni*, and is not easily identified in the field.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which states that *A. listeri* is distinctive, thus we conclude the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. listeri*'s distribution, habitat, and depth range. *Acropora listeri* is distributed from the Red Sea through the Indian Ocean to the southeast Pacific. The species has a very broad range overall, the 13th largest range of 114 *Acropora* species. Its predominant habitat is lower reef crests and upper reef slopes in strong wave action, and adjacent or similar habitats. Its depth range is from near the surface to 15 m deep.

The public comments did not provide any new or supplemental information on *A. listeri*'s distribution, habitat, or depth range. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 54 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 14. Wallace (1999b) reports its occurrence in 21 of her 29 Indo-Pacific areas (Wallace, 1999b), many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. listeri* at 105 million km<sup>2</sup>.

##### Demographic Information

The SRR and SIR provided the following information on *A. listeri*'s abundance. *Acropora listeri* has been reported as uncommon. This species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction.

The public comments did not provide any new or supplemental information on *A. listeri*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. listeri* occupied 5.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.35 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-

quantitative system, the species' abundance was characterized as "uncommon." and overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. listeri*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. listeri* occurs in many areas affected by these broad changes, and has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. listeri*'s life history. *Acropora listeri* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. listeri*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific

information on the effects of these threats on *A. listeri*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. listeri*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerability to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. listeri*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora listeri* has been rated as moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Done *et al.* (2003b) report 20 percent of *A. listeri* colonies were affected by bleaching on the Great Barrier Reef in 2002, which was 47 percent as much as the most affected species (Brown and Cossins, 2011).

With regard to disease, *A. listeri* has been rated as moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Skeletal Eroding Band is the most prevalent disease on the GBR, and it has been found in *A. listeri*. *Acropora* species with similar morphology to *A. listeri* had moderate susceptibility to this disease on the GBR, with a prevalence of 2.4 percent (Page and Willis, 2007). No other species-specific information is available for the susceptibility of *A. listeri* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. listeri* may be susceptible to the effects of ocean acidification, sedimentation, and nutrients, and predation. Thus, based on the available species-specific and genus information summarized above, *A. listeri* likely is highly susceptible to ocean warming, and also likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. listeri* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. listeri*. Criticisms of our approach

received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. listeri* occurs in 54 Indo-Pacific ecoregions that encompass 40 countries' EEZs. The 40 countries are Australia, Brunei, China, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Israel, Japan, Jordan, Kiribati, Malaysia, Marshall Islands, Mauritius, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan, Taiwan, Tanzania, Timor-Leste, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory, Pitcairn Islands), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms relevant to *A. listeri*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (30 percent with 8 percent limited in scope), coral collection (63 percent with 30 percent limited in scope), pollution control (45 percent with 8 percent limited in scope), fishing regulations on reefs (90 percent with 23 percent limited in scope), and managing areas for protection and conservation (95 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. listeri* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 30 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. listeri*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. listeri*. Its limited local distribution was also listed as a contributing factor to its threat of extinction. The SRR also listed factors that reduce the threat of extinction

including its broad geographic range and tolerance for high-energy environments.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. listeri*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution stretches from the Red Sea and east coast of Africa, across the Indian Ocean and over to the southeast Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from near the surface to 15 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes lower reef crests, upper reef slopes, and other habitats exposed to strong wave action, and its depth range is from near the surface to 15 m deep. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on

local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. In addition, reef zones with strong wave action experience high levels of mixing which can dilute adverse environmental conditions. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. listeri* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. aculeus* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information provided on *A. listeri*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Acropora listeri*'s distribution from the Red Sea across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous

habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora listeri*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events, as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. listeri* is not warranted for listing at this time under any of the listing factors.

#### *Acropora lokani*

##### Introduction

The SRR and SIR provided the following information on *A. lokani*'s morphology and taxonomy. Morphology was described as small bushy colonies of forked branches, and taxonomy was described as having no taxonomic issues but being similar in appearance to some other *Acropora* species.

The public comments did not provide supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which states that *A. lokani* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. lokani*'s distribution, habitat, and depth range. *Acropora lokani* occurs from central Indonesia to Fiji. The species has the 33rd smallest range of 114 *Acropora* species in a large study. However, as described below, this was an error, as *A. lokani* actually had the 30th smallest range in the study. *A. lokani* occurs in reef slope and back-reef habitats, including at least upper reef-slopes, mid-slopes, and lagoon patch reefs, and its depth range as 8 to 25 m.

The public comments and information we gathered provided information on the distribution of *A. lokani*. One public comment letter indicated that the range map for *A. lokani* mistakenly included American Samoa. We gathered supplemental information, including Veron (2014), which provides a much more detailed range map for this species than the maps used in the SRR. Veron reports that this species is confirmed in 14 of his 133 Indo-Pacific ecoregions is strongly predicted to be found in an additional six, and confirms that the species is not known to occur in American Samoa. Wallace (1999) reports its occurrence in four of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions. Richards (2009) calculated the geographic range of this species at over 5 million km<sup>2</sup>, which was the 30th smallest among the 114 *Acropora* species for which ranges were calculated, and 3.6 percent of the size of the largest range for any species. Richards *et al.* (Richards *et al.*, 2013a) calculate the range of this species as 8.5 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. lokani*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *A. lokani*'s abundance. *Acropora lokani* has been reported as uncommon, but sometimes common.

The public comments did not provide supplemental information on *A. lokani*'s

abundance. We gathered supplemental information, including Richards *et al.* (2013b), which concludes that this species is globally restricted, locally restricted, and locally rare, and thus in the rarest category of *Acropora* with the predicted consequence of global extinction. They placed 15 species in this category out of 85 species of *Acropora* (Richards *et al.*, 2013b). Veron (2014) reports that *A. lokani* occupied 2.75 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.44 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "sometimes common." Veron did not infer trends in abundance from these data.

Richards *et al.* (2008) reported that *A. lokani* had the eleventh lowest population of the 15 rare *Acropora* species they studied. Richards *et al.* (2008) gave the total world population of this species as about 18,960 +/-9480 colonies, and the effective population size (*i.e.*, a mathematical estimate of the size of the breeding population) as about 2,086 colonies. The calculation of the total world population of this species was flawed, since the area of 1 km<sup>2</sup> was given as 1,000 m<sup>2</sup> (Richards *et al.*, 2008: Appendix 1), when it is actually 1,000,000 m<sup>2</sup>. Thus, the correct population estimate is 1,000 times greater than stated, or a total population size of 18,960,000 colonies, and an effective population size of 2,086,000 colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. lokani*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparisons sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by harder coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from

a combination of global and local threats. Given that *A. lokani* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. lokani*'s life history. *Acropora lokani* is assumed to be a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. lokani*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. lokani*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. lokani*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. lokani*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora lokani* has been rated as moderately or highly susceptible to thermal bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on information from other *Acropora* species provided in the genus description above, *A. lokani* is likely highly susceptible to ocean warming, and likely has some susceptibility to disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. lokani* to the threats.

## Regulatory Mechanisms

In the proposed rule we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. lokani*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. lokani* occurs in 14 Indo-Pacific ecoregions that encompass nine countries' EEZs. The nine countries are Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Palau, Papua New Guinea, Philippines, Solomon Islands, and Timor-Leste. The regulatory mechanisms relevant to *A. lokani*, described first as a percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms are limited in scope, are as follows: General coral protection (33 percent with none limited in scope), coral collection (67 percent with 22 percent limited in scope), pollution control (33 percent with 22 percent limited in scope), fishing regulations on reefs (100 percent with none limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *A. lokani* are coral collection laws, reef fishing regulations, and area management for protection and conservation. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *A. lokani*.

## Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. lokani*, with the potential for extinction increased by the smallest effective population size of species with actual data, limited geographic and restricted latitudinal range, and also the small global distribution, small local distributions, and small local abundances.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species

abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. lokani*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited to parts of the Coral Triangle and the western equatorial Pacific Ocean. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range of eight to 25 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef-slopes, mid-slopes, and lagoon patch reefs. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its effective population size of two million colonies, combined with the location of its range, exacerbates vulnerability to extinction because increasingly severe conditions within the limited species range are likely to affect a high proportion of its effective population at any given point in time.

## Listing Determination

In the proposed rule using the determination tool formula approach, *A. lokani* was proposed for listing as endangered because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); rare

generalized range wide abundance (E); overall narrow distribution (based on narrow geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. lokani* from endangered to threatened. No supplemental information or public comments changed our assessment of the type and severity of threats affecting *A. lokani*. Rather, we made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information provided above on *A. lokani*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora lokani* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C) ocean acidification (E), trophic effects of fishing (A), nutrients (A, E), and predation (C). These threats are expected to continue and increase into the future. In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D).

(2) *Acropora lokani*'s distribution is mostly constrained to the Coral Triangle and western equatorial Pacific, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Acropora lokani*'s absolute abundance is estimated to be 19 million colonies, however its estimated effective population size is much lower at around two million genetically distinct colonies. Considering the limited range of this species in an area where severe and increasing impacts are predicted,

this level of abundance leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from compensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. lokani*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. lokani*'s distribution is constrained mostly to the Coral Triangle which increases its extinction risk as described above, its habitat includes sheltered lagoon patch reefs and other shallow reef environments. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) *Acropora lokani*'s absolute abundance is tens of millions of colonies, and effective population size is still millions of colonies which allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of

one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. lokani*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora microclados*

##### Introduction

The SRR and SIR provided the following information on *A. microclados*' morphology and taxonomy. Morphology was described as plates up to 1 m diameter, with short, uniform, evenly spaced, tapered branchlets up to 10 mm thick at the base, and taxonomy was described as having no taxonomic issues but that it is most similar to *A. massawensis*, *A. lamarcki*, and *A. macrostoma*.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which states that *A. microclados* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. microclados*' distribution, habitat, and depth range. *Acropora microclados* is distributed from the Red Sea, to the central Pacific. The species has a broad range overall with the 20th largest range of 114 *Acropora* species. Its habitat is predominantly lower reef crests, upper reef slopes, and mid-slope terraces, and its depth range is from five to 20 m.

The public comments provided the following supplemental information on *A. microclados*' distribution. One public comment stated that the species has not been confirmed in the Commonwealth of the Northern Mariana Islands by expert Richard H. Randall, in contradiction to the SRR. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 56 of his 133

Indo-Pacific ecoregions, and strongly predicted to be found in an additional 18. Wallace (1999b) reports its occurrence in 21 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. microclados* at 100 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. microclados*' habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. microclados*' abundance. *Acropora microclados* has been reported as uncommon. This species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction. The public comments did not provide any new or supplemental information on *A. microclados*' abundance. We gathered supplemental information, including Veron (2014), which reports that *A. microclados* occupied 15.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.51 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was also described as "usually uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. microclados*, the overall decline in abundance ("Percent Population Reduction") was estimated at 33 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years

(Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. microclados* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. microclados*' life history. *Acropora microclados* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. microclados*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. microclados*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. microclados*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments provided some supplemental information on *A. microclados*' threat susceptibilities. One comment stated that *A. microclados* is more susceptible to predation than indicated in the proposed rule because of the overlap in the depth ranges of this species with crown of thorns starfish. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora microclados* has been rated as moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Supplemental species-specific information is available on the susceptibility of *A. microclados* to ocean warming. In a study of ocean warming of *Acropora* species on the GBR, *A. microclados* had low bleaching

susceptibility: of 48 *Acropora* species, only three species had no bleaching, including *A. microclados* (Done *et al.*, 2003b). In a study of ocean warming of *Acropora* species in Kimbe Bay, Papua New Guinea, *A. microclados* had moderate bleaching susceptibility: of 16 *Acropora* species, *A. microclados* had the sixth highest level of bleaching, with seven percent mortality compared to 40 percent for the highest species, and was rated "moderate" on a scale of severe, high, moderate, and least (Bonin, 2012). No other species-specific information is available for the susceptibility of *A. microclados* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. microclados* may be susceptible to ocean warming, disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. Thus, based on the available species-specific and genus information summarized above, *A. microclados* likely has some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. microclados* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. microclados*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. microclados* occurs in 56 Indo-Pacific ecoregions that encompass 37 countries' EEZs. The 37 countries are Australia, China, Comoros Islands, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Japan, Jordan, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sudan, Taiwan, Thailand, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory, Pitcairn Islands), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms relevant to *A. microclados*, described first as the percentage of the above countries that utilize them to any degree and second,

as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (27 percent with 5 percent limited in scope), coral collection (62 percent with 30 percent limited in scope), pollution control (46 percent with 8 percent limited in scope), fishing regulations on reefs (89 percent with 16 percent limited in scope), and managing areas for protection and conservation (95 percent with 11 percent limited in scope). The most common regulatory mechanisms in place for *A. microclados* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 30 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. microclados*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. microclados*. The threat of extinction may be increased to by its limited local distribution and uncommon local abundance. The SRR also listed factors that reduce the threat of extinction including the species' geographic and depth ranges.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. microclados*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to

extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from five to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat is predominantly lower reef crests, upper reef slopes, and mid-slope terraces. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. In addition, two species-specific studies indicate that, unlike many other *Acropora* species, *A. microclados* is not highly susceptible to warming-induced bleaching, one of the primary threats identified for corals.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. microclados* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. microclados*

from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. microclados*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) While the species has some susceptibility to bleaching, unlike most other *Acropora* species, it does not appear to be highly susceptible to this threat, as shown by two newly available species-specific studies;

(2) *Acropora microclados*' distribution from the Red Sea across the Indian Ocean and most of the Pacific Ocean includes is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(3) *Acropora microclados*' absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(4) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events, as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased

severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. microclados* is not warranted for listing at this time under any of the listing factors.

#### *Acropora palmerae*

##### Introduction

The SRR and SIR provided the following information on *A. palmerae*'s morphology and taxonomy. Morphology was described as encrusting with or without short, irregularly shaped branches. Colonies seldom exceed 1 m across. There is doubt as to whether *A. palmerae* is a separate species or a strong-water form of *A. robusta*; however, in the absence of genetic information, the BRT considered it a valid species. *A. palmerae* is like the encrusting base of *A. robusta*, but it has smaller branches, if any.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, including Wallace (1999b) and Veron (Veron, 2000), who both considered it a valid species. In addition, Veron (2014) states that *A. palmerae* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. palmerae*'s distribution, habitat, and depth range. *Acropora palmerae* is distributed from the northern Indian Ocean to the central Indo-Pacific and central Pacific. The species has a moderate range overall,

with the 52nd largest range of 114 *Acropora* species. The SRR and SIR reported that it occurs in most reef slope and back-reef habitats, including upper reef slopes, lower reef crests, and reef flats, with a depth range of five to 20 m. The public comments and information we gathered provided the following information on *A. palmerae*'s distribution. One public comment stated that the depth distribution appears to be restricted to depths of less than 12 m, based on observations in Guam and reports from elsewhere. We gathered supplemental information, including observations that the depth range of *A. palmerae* in American Samoa is low tide to about 5 m deep, and on Tinian Island in the Marianas it is from about 2 to 5 m (D. Fenner, pers. communication). Thus, based on all the available information, *A. palmerae*'s habitat includes upper reef slopes, mid-slope terraces, lower reef crests, and reef flats. Based on all the information from across its range, we consider its depth range to be from two to 20 m depth. Veron (2014) reports that *A. palmerae* is confirmed in 42 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 17. Wallace (1999b) reports its occurrence in seven of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range at over 60 million km<sup>2</sup>.

#### Demographic Information

The SRR and SIR provided the following information on *A. palmerae*'s abundance. *Acropora palmerae* has been reported as uncommon.

The public comments did not provide any new or supplemental information on *A. palmerae*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. palmerae* occupied 2.7 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.81 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data. *Acropora palmerae* can be abundant within a very narrow depth range in shallow water (as it is on the west coast of Tinian in the Marianas), which may be missed in some surveys (D. Fenner, personal comm.). As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute

abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. palmerae*, the overall decline in abundance ("Percent Population Reduction") was estimated at 39 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. palmerae* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. palmerae*'s life history. Like most other *Acropora* species, *A. palmerae* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. Unlike most other *Acropora* species, colonies of *A. palmerae* can be entirely encrusting with no branches (or colonies may have short, irregularly-shaped branches). The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. palmerae*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. palmerae*. We interpreted the threat susceptibility and exposure

information from the SRR and SIR in the proposed rule for *A. palmerae*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. palmerae*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora palmerae* has been rated as moderately or highly susceptible to thermal bleaching and coral disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. palmerae* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. palmerae* is likely highly susceptible to ocean warming, and also has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. palmerae* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. palmerae*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. palmerae* occurs in 42 Indo-Pacific ecoregions that encompass 28 countries' EEZs. The 28 countries are Australia, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (including Andaman and Nicobar Islands), Indonesia, Japan, Marshall Islands, Mauritius, Myanmar, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Seychelles, Solomon Islands, Sri Lanka, Taiwan, Thailand, Timor-Leste, Tonga, Tuvalu, United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *A. palmerae*, described first as the percentage of the above countries that utilize them, to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General

coral protection (36 percent with 11 percent limited in scope), coral collection (57 percent with 29 percent limited in scope), pollution control (39 percent with 11 percent limited in scope), fishing regulations on reefs (96 percent with 11 percent limited in scope), and managing areas for protection and conservation (96 percent with 4 percent limited in scope). The most common regulatory mechanisms in place for *A. palmerae* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. palmerae*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. palmerae*. It listed factors that reduce the threat of extinction including its very broad geographic range, the fact that it is often common and sometimes abundant, and the broad range of suitable habitat types for *A. palmerae*.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. palmerae*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and

western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from the surface to as much as 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes, mid-slope terraces, lower reef crests, and reef flats in depth ranging from two to 20 m depth. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Reef zones subject to high wave action also experience high levels of mixing which can dilute adverse environmental conditions. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. palmerae* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderately wide distribution (based on moderate geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. palmerae* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a

threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. palmerae*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Acropora palmerae*'s distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the wide variety of habitat types it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora palmerae*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events, as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout

its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. palmerae* is not warranted for listing at this time under any of the listing factors.

#### *Acropora paniculata*

##### Introduction

The SRR and SIR provided the following information on *A. paniculata*'s morphology and taxonomy. Morphology was described as large plates or tables that are 25 mm thick and frequently greater than 1 m across, and taxonomy was described as having no taxonomic issues, but it is quite similar to *A. cytherea* and similar to *A. jacquelineae*.

The public comments and information we gathered provided information on morphology and taxonomy of *A. paniculata*. One public comment stated that in Hawaii, colony morphology of *A. paniculata* resembles that of *A. cytherea*, but that *A. paniculata* occurs at greater depths than *A. cytherea*, which opens the possibility of them being the same species that changes growth forms at different depths. We gathered supplemental information, including Veron (2014), which states that *A. paniculata* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. paniculata*'s distribution, habitat, and depth range. *Acropora paniculata* is distributed from the Red Sea and Indian Ocean to the west and central Pacific, including within the Mariana Islands. The species has a moderately broad range, the 40th largest range of 114 *Acropora* species. Its habitat includes numerous reef slope and back-reef habitats, including at least upper reef slopes, mid-slope terraces, lower reef slopes, and sheltered lagoons, and its depth range is 10 to 35 m.

The public comments and the supplemental information provided the following information on *A.*

*paniculata*'s distribution. One public comment stated that occurrence of *A. paniculata* within the Mariana Islands has not been confirmed by expert Richard H. Randall, in contradiction to the SRR. We gathered supplemental information, including Veron (2014), which reports that *A. paniculata* is confirmed in 51 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 15. Wallace (1999b) reports its occurrence in 19 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range at 80 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. paniculata*'s habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. paniculata*'s abundance. *Acropora paniculata* has been reported as uncommon to rare (Veron, 2000). Richards (2009) concluded that this species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction.

The public comments and information we gathered provided the following information on *A. paniculata*'s abundance. One public comment stated that Fenner's 2005 book *Corals of Hawaii* notes that in the Hawaiian Islands, *A. paniculata* is "not common," which the commenter argued demonstrates that the species is not rare, at least in Hawaii. We gathered supplemental information, including observations made in 2014 that *A. paniculata* is one of the most common corals in the Chagos Islands in the Indian Ocean, where it has recovered rapidly from the 1998 mass bleaching event (D. Fenner, personal comm.). Veron (2014) reports that *A. paniculata* occupied 14.3 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.43 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common," and overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. paniculata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent in the study. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Zsmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. paniculata* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *A. paniculata*'s life history. Like most other *Acropora* species, *A. paniculata* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

##### Susceptibility to Threats

To describe *A. paniculata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. paniculata*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. paniculata*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of

fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. paniculata*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora paniculata* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. paniculata* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. paniculata* likely is highly susceptible to ocean warming, and also has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. paniculata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. paniculata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. paniculata* occurs in 51 Indo-Pacific ecoregions that encompass 37 countries' EEZs. The 37 countries are Australia (including Cocos-Keeling Islands), China, Comoros Islands, Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Israel, Japan, Jordan, Kiribati, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, Nauru, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Sudan, Taiwan, Thailand, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (Hawaii, American Samoa, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *A. paniculata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (24 percent with 3 percent limited in scope), coral

collection (59 percent with 30 percent limited in scope), pollution control (43 percent with 8 percent limited in scope), fishing regulations on reefs (89 percent with 22 percent limited in scope), and managing areas for protection and conservation (95 percent with 11 percent limited in scope). The most common regulatory mechanisms in place for *A. paniculata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 30 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. paniculata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. paniculata*. It listed factors that reduce the threat of extinction including the moderately wide geographic range, presence in deeper habitats, and being common in New Guinea though rare elsewhere.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. paniculata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some

areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from 10 to 35 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slope terraces, lower reef slopes, and sheltered lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. paniculata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. paniculata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A.*

*paniculata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Acropora paniculata*'s distribution from the Red Sea across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora paniculata*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in

danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. paniculata* is not warranted for listing at this time under any of the listing factors.

#### *Acropora pharaonis*

##### Introduction

The SRR and SIR provided the following information on *A. pharaonis*' morphology and taxonomy. Morphology was described as large horizontal tables or irregular clusters of horizontal or upright interlinked contorted branches, and taxonomy was described as having no taxonomic issues but being similar in appearance to *Acropora clathrata* and *Acropora plumosa*.

The public comments did not provide supplemental information on morphology or taxonomy. We gathered supplemental information, including that *A. pharaonis* is recognized as valid by experts (Veron, 2000; Veron, 2014; Wallace, 1999a). Veron (2014) also states that records of this species in the Pacific by other authors are likely to be another, probably undescribed species. However, we conclude the species can be identified by experts, thus the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. pharaonis*' distribution, habitat, and depth range. *Acropora pharaonis* has a disjoint distribution, being present in the Red Sea and western/northern Indian Ocean, and areas in the Pacific Ocean. It notes that IUCN stated that there are doubts about the Pacific records. The species has the 14th smallest range of 114 *Acropora* species. Its habitat includes reef slope and back-reef habitats, including at least upper reef slopes, mid-slope terraces, and lagoons, and its depth range is 5 to 25 meters.

The public comments did not provide supplemental information on *A. pharaonis*' distribution. We gathered supplemental information, including Veron (2014), which reports that *A. pharaonis* is confirmed in 11 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional eight. All 19 of these ecoregions are in the Indian Ocean. Wallace (1999b) reports its occurrence in six of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions, stating that, "This unusual species appears to be restricted to the Red Sea." Richards

(2009) estimated its range at 1.4 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. pharaonis*' habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. pharaonis*' abundance. *Acropora pharaonis* has been reported as common. The public comments did not provide supplemental information on *A. pharaonis*' abundance. We gathered supplemental information, including Veron (2014), which reports that *A. pharaonis* occupied 3.6 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.80 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "common in the Red Sea, uncommon elsewhere." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. pharaonis*, the overall decline in abundance ("Percent Population Reduction") was estimated at 30 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by harder coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. pharaonis* occurs in areas affected by these broad changes, and has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise

quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. pharaonis*' life history. *Acropora pharaonis* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. pharaonis*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR also reported that *A. pharaonis* was locally extirpated in the SE Arabian Gulf after the combined impacts of the 1996 and 1998 bleaching events, and that the species is susceptible to several diseases that affect reproduction including reduced fecundity. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. pharaonis*' vulnerabilities as follows: High vulnerability to ocean warming and disease, moderate vulnerabilities to ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide supplemental information on *A. pharaonis*' threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora pharaonis* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. pharaonis* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. pharaonis* likely has high susceptibility ocean warming, and also likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, and collection and trade. Based on the available information, high susceptibility to disease (as stated in the proposed rule for this species) is not supported. The available information does not support more precise ratings of the susceptibilities of *A. pharaonis* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. pharaonis*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. pharaonis* occurs in 11 Indo-Pacific ecoregions that encompass 21 countries' EEZs. The 21 countries are Bahrain, Djibouti, Egypt, Eritrea, France (French Pacific Island Territories), India, Iran, Israel, Jordan, Kuwait, Madagascar, Maldives, Mauritius, Qatar, Saudi Arabia, Seychelles, Somalia, Sri Lanka, Sudan, United Arab Emirates, and Yemen. The regulatory mechanisms relevant to *A. pharaonis*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (29 percent with 10 percent limited in scope), coral collection (43 percent with five percent limited in scope), pollution control (52 percent with five percent limited in scope), fishing regulations on reefs (76 percent with 24 percent limited in scope), and managing areas for protection and conservation (71 percent with 14 percent limited in scope). The most common regulatory mechanisms in place for *A. pharaonis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. pharaonis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. pharaonis*. This is exacerbated by its restricted range and the need for protected habitats. The SRR also listed factors that reduce the threat of extinction including its moderate depth range (5 m to 25 m) and its common abundance levels in the Red Sea.

Subsequent to the proposed rule, we received and gathered supplemental

species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. pharaonis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes the Red Sea and Arabian Gulf, but relatively few islands. This exacerbates vulnerability to extinction over the foreseeable future because it is restricted a portion of the Indian Ocean with a limited amount of island and offshore habitat, and includes areas projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century (*i.e.*, the Red Sea and the Arabian Gulf). Its depth range of five to 25 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes reef slope and back-reef habitats, including at least upper reef slopes, mid-slope terraces, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. There is not enough information about its abundance to determine if it moderates or exacerbates extinction: It is common in the Red Sea, uncommon elsewhere, and has at least millions of colonies, but the Red Sea and Arabian Gulf portions of the population are expected to be severely impacted by threats over the foreseeable future. While depth distribution and habitat variability moderate vulnerability to extinction, the combination of its

geographic distribution and high susceptibility to ocean warming are likely to be more influential to the status of this species over the foreseeable future, because of the projected severity of ocean warming in much of the species' range in the foreseeable future, and its high susceptibility to this threat.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. pharaonis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E) and disease (C); moderate vulnerability to acidification (E); common generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we confirmed the species' proposed listing determination as threatened. Based on the best available information provided above on *A. pharaonis*' spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus still warrants listing as threatened at this time, because:

(1) *Acropora pharaonis* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of fishing (A), predation (C), and nutrients (A, E). These threats are expected to continue and increase into the future. In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D).

(2) *Acropora pharaonis*' distribution is constrained entirely to the Red Sea, Arabian Gulf, and western and central Indian Ocean where projections of ocean warming and local threats (e.g., land-based sources of pollution) are both frequent and severe over the foreseeable future compared to other areas of the Indo-Pacific. A range constrained to a particular geographic area that is likely to experience severe and worsening threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Acropora pharaonis* suffered documented local extirpation in the southeast Arabian Gulf after the combined impacts of the 1996 and 1998 bleaching events, providing evidence that this species has already been severely impacted by ocean warming in some parts of its range.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. pharaonis*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. pharaonis*' distribution is only the Indian Ocean and the Middle East, which increases its extinction risk as described above, its habitat includes sheltered lagoon patch reefs and other shallow reef environments. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence that the species is so spatially fragmented or geographically constrained that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) *Acropora pharaonis* absolute abundance is at least millions of colonies, which allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of depensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A.*

*pharaonis*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora polystoma*

##### Introduction

The SRR and SIR provided the following information on *A. polystoma*'s morphology and taxonomy. Morphology was described as irregular clumps or plates with tapered branches of similar length and shape, and being similar to *A. massawensis* and *A. polystoma*. The taxonomy was described as not having much uncertainty, except in the Mariana Islands where specimens previously identified as *A. polystoma* may be a different species.

The public comments and information we gathered provided information on morphology or taxonomy of *A. polystoma*. One public comment stated that specimens of *A. polystoma* in Guam may represent a different species. We gathered supplemental information, including Veron (2014), which states that *A. polystoma* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. polystoma*'s distribution, habitat, and depth range. *Acropora polystoma* is distributed from the Red Sea to the Indian Ocean to the central Pacific. The species has the 28th largest range of 114 *Acropora* species. Its habitat includes areas exposed to strong wave action, including upper reef slopes, lower reef crests, reef flats, and other habitats, and its depth range is three to 10 meters.

The public comments did not provide any new or supplemental information on *A. polystoma*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 48 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 19. Wallace (1999b) reports its occurrence in 19 of her 29 Indo-Pacific areas, many of which are significantly larger than Veron's ecoregions. Richards (2009) calculated

the geographic range of *A. polystoma* at 85 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. polystoma*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *A. polystoma*'s abundance. *Acropora polystoma* has been reported as uncommon.

The public comments did not provide any new or supplemental information on *A. polystoma*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. polystoma* occupied 6.7 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.74 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. polystoma*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. polystoma* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a

precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. polystoma*'s life history. *Acropora polystoma* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. polystoma*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. polystoma*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. polystoma*'s vulnerabilities as follows: High vulnerability to ocean warming and disease, moderate vulnerabilities to ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. polystoma*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *A. polystoma* has been rated as moderately or highly susceptible to bleaching and warming-induced disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. polystoma* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. polystoma* likely has high susceptibility to ocean warming, and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, and collection and trade. Based on the available information, high susceptibility to disease, as stated in the proposed rule for this species, is not supported. The available information does not support more precise ratings of the susceptibilities of *A. polystoma* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. polystoma*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. polystoma* occurs in 48 Indo-Pacific ecoregions that encompass 41 countries' EEZs. The 41 countries are Australia, Brunei, China, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Israel, Japan, Jordan, Kenya, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Sudan, Taiwan, Tanzania, Thailand, Timor-Leste, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms relevant to *A. polystoma*, described first as the percentage of the above countries that utilize them to any degree and second, the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (24 percent with two percent limited in scope), coral collection (63 percent with 32 percent limited in scope), pollution control (39 percent with seven percent limited in scope), fishing regulations on reefs (90 percent with 20 percent limited in scope), and managing areas for protection and conservation (95 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. polystoma* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 32 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. polystoma*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated

that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. polystoma*, which is exacerbated by the relatively restricted depth range and the uncommon abundance. It listed factors that reduce the threat of extinction including the wide geographic range, and the intertidal habitat which may indicate potentially increased tolerance.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. polystoma*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth distribution down to 10 meters may exacerbate the species exposure to some threats that are more severe in shallower water. Shallow reef environments can experience frequent changes in environmental conditions, extremes, high irradiance, and multiple stressors simultaneously. However, its habitat includes areas exposed to strong wave action, including upper reef slopes, lower reef crests, reef flats, and other high energy habitats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. In addition, areas of high currents and/or

wave action experience high levels of mixing which can dilute adverse environmental conditions. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. polystoma* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. polystoma* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. polystoma*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Acropora polystoma*'s distribution across the Red Sea, Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As

explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora polystoma*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) *A. polystoma* is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future as global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. polystoma* is not warranted for listing at this time under any of the listing factors.

#### *Acropora retusa*

##### Introduction

The SRR and SIR provided the following information on *A. retusa*'s morphology and taxonomy. The morphology was described as flat plates with short thick digitate branchlets and taxonomy was described as having no taxonomic issues, but it is similar to *Acropora branchi*, *Acropora gemmifera*, and *Acropora monticulosa*.

The public comments did not provide any new or supplemental information on morphology or taxonomy of *A.*

*retusa*. We gathered supplemental information, which indicated that while there is some taxonomic uncertainty for this species, it is recognized as valid by experts (Veron, 2000; Wallace, 1999a). Veron (2014) states that *A. retusa* is readily confused with other *Acropora*, but we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. retusa*'s distribution, habitat, and depth range. *Acropora retusa* is distributed from the Red Sea and the Indian Ocean to the central Pacific. The species has the 52nd largest range of 114 *Acropora* species. Its habitat includes shallow reef slope and back-reef areas, such as upper reef slopes, reef flats, shallow lagoons, and its depth range is one to five meters.

The public comments did not provide any new or supplemental information on *A. retusa*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 23 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 21. Wallace (1999b) reports its occurrence in five of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) estimated its range at 68 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. retusa*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *A. retusa*'s abundance. *Acropora retusa* has been reported as common in South Africa and uncommon elsewhere. The public comments did not provide any new or supplemental information on *A. retusa*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. retusa* occupied 0.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.21 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare." Overall abundance was described as "common in South Africa, rare elsewhere." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute

abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. retusa*, the overall decline in abundance ("Percent Population Reduction") was estimated at 49 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 18 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. retusa* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited amount of species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. retusa*'s life history. *Acropora retusa* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. retusa*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. retusa*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. retusa*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of

fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. retusa*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora retusa* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. retusa* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. retusa* is likely highly susceptible to ocean warming, and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. retusa* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. retusa*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. retusa* occurs in 23 Indo-Pacific ecoregions that encompass 26 countries' EEZs. The 26 countries are Brunei, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India, Indonesia, Japan, Kenya, Madagascar, Malaysia, Mauritius, Mozambique, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Samoa, Seychelles, Solomon Islands, South Africa, Sri Lanka, Tanzania, Tonga, Tuvalu, United States (CNMI, Guam, American Samoa), and Vietnam. The regulatory mechanisms relevant to *A. retusa*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (19 percent with eight percent limited in scope), coral collection (58 percent with 35 percent limited in scope), pollution control (38 percent with 12 percent limited in scope), fishing regulations on reefs (96 percent with 23 percent limited in scope), and managing areas for protection and conservation (100

percent with none limited in scope). The most common regulatory mechanisms in place for *A. retusa* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 35 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. retusa*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the high bleaching rate of the *Acropora* genus is the primary known threat of extinction for *A. retusa*. The species' rarity adds to its risk of extinction. The SRR also listed factors that reduce the threat of extinction including its geographic range and its occurrence in tidal pools (suggesting high physiological stress tolerance).

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. retusa*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so

portions of the population in these areas will be less exposed to severe conditions. Its depth range of zero to five meters exacerbates vulnerability to extinction over the foreseeable future. Shallow reef areas are often subjected to highly variable environmental conditions, extremes, high irradiance, and simultaneous effects from multiple stressors, both local and global in nature. A species restricted to such shallow depths is likely to have a high proportion of individuals exposed to higher levels of irradiance and other threats that are more severe in shallow habitats. Its habitat includes shallow reef slope and back-reef areas, such as upper reef slopes, reef flats, and shallow lagoons. While this generally moderates vulnerability to extinction for most species that can occupy a diverse set of habitat types, in this case, habitat heterogeneity likely does not provide much moderation of exposure to threats because of the shallow depth restriction for this species. Its absolute abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. However, its qualitative abundance is described as rare, which combined with its restricted depth distribution indicates it is likely that a high proportion of individuals will be affected by threats that are typically more severe in shallow habitats at any given point in time.

#### Listing Determination

In the proposed rule using the listing determination tool approach, *A. retusa* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we maintain the species' proposed listing determination as threatened. Based on the best available information provided above on *A. retusa*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus

warrants listing as threatened at this time, because:

(1) *Acropora retusa* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of fishing (A), predation (C), and nutrients (A, E). These threats are expected to continue and increase into the future. In addition, existing regulatory mechanisms addressing global threats that contribute to extinction risk for this species inadequate (D);

(2) *Acropora retusa* is restricted to shallow habitat (zero to five meters), where many global and local threats may be more severe, especially near populated areas. Shallow reef areas are often subjected to highly variable environmental conditions, extremes, high irradiance, and simultaneous effects from multiple stressors, both local and global in nature. A limited depth range also reduces the absolute area in which the species may occur throughout its geographic range, and indicates that a large proportion of the population is likely to be exposed to threats that are worse in shallow habitats, such as simultaneously elevated irradiance and seawater temperatures, as well as localized impacts; and

(3) *Acropora retusa*'s abundance is considered rare overall. This level of abundance, combined with its restricted depth distribution where impacts are more severe, leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from compensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. retusa*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) *Acropora retusa*'s distribution from South Africa to the Pitcairn Islands is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and

other areas. This distribution reduces exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) While *Acropora retusa* is limited to shallow depths, which increases its extinction risk as described above, its geographic range encompasses heterogeneous habitat, the benefits of which are explained in detail in the Coral Habitat sub-section above, across almost half of the coral reef area in the Indo-Pacific, and there is no evidence to suggest that it is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(3) While *Acropora retusa*'s qualitative abundance is characterized as rare, its absolute abundance is at least millions of colonies. Additionally, *A. retusa* is considered common in a portion of its range (South Africa), indicating it is not of such low abundance that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. retusa*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora rudis*

##### Introduction

The SRR and SIR provided the following information on *A. rudis*' morphology and taxonomy. Morphology

was described as arborescent with large, tapered, prostate branches, reaching a maximum size of 50 cm and taxonomy was described as having no taxonomic issues but being similar in appearance to *A. hemprichii* and *A. variolosa*.

The public comments and information we gathered provided information on morphology or taxonomy. One public comment stated that specimens collected in American Samoa and identified by the American Samoa Department of Marine and Water Resources as *A. rudis* appear to be *A. aculeus*, thereby illustrating the species identification uncertainties associated with this species. We gathered supplemental information, including Veron (2014), which states that *A. rudis* is readily confused with *Acropora schmitti* in shallow habitats, but is very distinctive otherwise, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. rudis*' distribution, habitat, and depth range. *Acropora rudis*' distribution has long been thought by Veron and others to be restricted to the northeastern Indian Ocean, with recent reports by Fenner suggesting it may also occur in New Caledonia and the Samoas. The species has the 24th smallest range of 114 *Acropora* species. Its predominant habitat is lower reef crests and upper reef slopes in three to 15 m of depth.

The public comments did not provide supplemental information on *A. rudis*' distribution. We gathered supplemental information, including Veron (2014), which provides much more detailed range map for this species than the maps used in the SRR. Veron reports that this species is confirmed in seven of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional two. Veron (2014) does not show it in New Caledonia and the Samoas, apparently because he does not believe there is enough information available to strongly predict its occurrence there. Wallace (1999b) reports its occurrence in four of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. rudis* at two million km<sup>2</sup>, which was the 24th smallest range of the 114 *Acropora* species examined. The public comments and information we gathered provided nothing additional on *A. rudis*' habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. rudis*' abundance. *Acropora rudis* has been reported as uncommon, however, it has been noted to comprise as much as half of the *Acropora* in some areas.

The public comments did not provide supplemental information on *A. rudis*' abundance. We gathered supplemental information, including Veron (2014), which reports that *A. rudis* occupied 0.1 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.25 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare." Overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. Other information indicates that *A. rudis* can be locally common, as it has been reported to comprise as much as half of the *Acropora* in the area south of the Hikkaduwa Nature Reserve in Sri Lanka (Rajasuriya, 2002). As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. rudis*, the overall decline in abundance ("Percent Population Reduction") was estimated at 59 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 22 percent. This estimated decline is approximately 50 percent higher than most other Indo-Pacific *Acropora* species included in the paper, apparently because of the combined restricted geographic and depth ranges (Carpenter *et al.*, 2008). However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local

threats. Given that *A. rudis* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. rudis*' life history. There is no information available on the reproductive biology of *A. rudis*, but all other *Acropora* studied to date are hermaphroditic broadcast spawners. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. rudis*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, and nutrients. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. rudis*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. rudis*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide supplemental information on *A. rudis*' threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora rudis* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. rudis* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. rudis* is likely highly susceptible to ocean warming, and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. rudis* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. rudis*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. rudis* occurs in seven Indo-Pacific ecoregions that encompass eight countries' EEZs. The eight countries are Bangladesh, India (Andaman and Nicobar Islands), Indonesia, Malaysia, Maldives, Myanmar, Sri Lanka, and Thailand. The regulatory mechanisms relevant to *A. rudis*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (25 percent with 13 percent limited in scope), coral collection (38 percent with 13 percent limited in scope), pollution control (50 percent with 13 percent limited in scope), fishing regulations on reefs (100 percent with 25 percent limited in scope), and managing areas for protection and conservation (88 percent with 13 percent limited in scope). The most common regulatory mechanisms in place for *A. rudis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species. General coral protection laws are much less common regulatory mechanisms for the management of *A. rudis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk of *A. rudis* include the relatively high susceptibility of the genus *Acropora* to common threats, and a particularly narrow and somewhat disjointed biogeographic range with limited latitudinal extent. They stated that there are no factors that notably reduce the threat of extinction.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat

susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. rudis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes the Maldives and parts of the northeastern Indian Ocean. This range exacerbates vulnerability to extinction over the foreseeable future because it is restricted to an area projected to experience severe climate change and localized impacts within the foreseeable future. Its depth range is three to 15 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus will be more severely affected by warming-induced bleaching. Its habitat includes lower reef crests and upper reef slopes. This moderates vulnerability to extinction over the foreseeable future because upper reef slopes are physically diverse and widespread reef areas, thus the species occurs in reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. It is rare, but has at least millions of colonies. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species

occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus will be more severely affected by warming-induced bleaching. Its absolute abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. However, its qualitative abundance is described as rare, which combined with its restricted depth distribution indicates it is likely that a high proportion of individuals will be affected by threats that are typically more severe in shallow habitats at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. rudis* was proposed for listing as endangered because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. rudis* from endangered to threatened. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information provided above on *A. rudis*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora rudis* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of fishing (A), predation (C), and nutrients (A, E). These threats are expected to continue and increase into the future. In addition, existing regulatory mechanisms to address global threats

that contribute to extinction risk for this species are inadequate (D);

(2) *Acropora rudis*' geographic distribution is restricted to the Maldives and northeastern Indian Ocean. While coral reefs in this area are projected to experience climate change effects later than the average predictions of severe conditions, it is nevertheless projected to experience severe impacts from combined climate change and localized human impacts for coral reefs within the foreseeable future. In addition, its range is constrained to a particular geographic area such that a high proportion of the population of this species is likely to be exposed to threats that occur throughout this range over the foreseeable future; and

(3) While *A. rudis*' abundance can be locally common, overall it is considered uncommon or rare, which means it does not possess as much buffering capacity in the form of variability in response between individuals or absolute abundance that would be afforded to a more abundant or common species. Considering the limited range of this species, this level of abundance leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from compensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. rudis*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. rudis*' distribution is restricted to the Maldives and northeastern Indian Ocean, its habitat is upper reef slopes of fringing reefs. This moderates vulnerability to extinction currently because the species occurs in common and variable habitats that are predicted, on local and regional scales, to experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest it is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events

currently pose a high risk to the survival of the species; and

(2) *Acropora rudis*' abundance is locally common in portions of its range, it has at least millions of colonies, and there is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events;

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. rudis*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.* GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora speciosa*

##### Introduction

The SRR and SIR provided the following information on *A. speciosa*'s morphology and taxonomy. Morphology was described as thick cushions or bottlebrush branches and taxonomy was described as having no taxonomic issues but being similar in appearance to *A. echinata* and *A. granulosa*.

The public comments did not provide supplemental information on morphology or taxonomy. We gathered supplemental information, including by Wallace (1999b), indicating species identification uncertainty for *A. speciosa*. However, Veron (2014) states that *A. speciosa* is distinctive so we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. speciosa*'s distribution, habitat, and depth range. *Acropora speciosa* is distributed from Indonesia to French Polynesia. The

species has the 51st smallest range of 114 *Acropora* species. It occurs on lower reef slopes and walls, especially those characterized by clear water and high *Acropora* diversity on steep slopes. Its depth range is 12 to 40 meters, and it has been found in mesophotic habitats.

The public comments did not provide supplemental information on *A. speciosa*'s distribution. We gathered supplemental information, including Veron (2014), which reports that *A. speciosa* is confirmed in 26 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 12. Wallace (1999b) reports its occurrence in 10 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) estimated its range at 20 million km<sup>2</sup>. The species was tentatively identified in mesophotic assemblages in American Samoa: "Shallow, plate-like reefs (more than 50 m) were comprised mostly of *Acropora* spp., possibly *A. clathrata*, *A. speciosa*, and *A. crateriformis*" (Bare *et al.*, 2010). The public comments and information we gathered provided nothing additional on *A. speciosa*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *A. speciosa*'s abundance. *Acropora speciosa* has been reported as uncommon.

The public comments did not provide supplemental information on *A. speciosa*'s abundance. We gathered supplemental information, including Richards *et al.* (2013b), which concludes that this species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction. Veron (2014) reports that *A. speciosa* occupied 8.3 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.60 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was described as "usually uncommon." Veron did not infer trends in abundance from these data.

Richards *et al.* (2008) reported that *A. speciosa* had the ninth smallest population of the 15 rare *Acropora* species they studied. Richards *et al.* (2008: Appendix 1) gave the total world population of this species as 10,942 ± 5,471 colonies, and the effective population size (*i.e.*, a mathematical estimate of the size of the breeding

population) as 1,204 colonies. The calculation of the total world population of this species was flawed, since the area of 1 km<sup>2</sup> was given as 1,000 m<sup>2</sup>, when it is actually 1,000,000 m<sup>2</sup>. Thus, the correct population estimate is 1,000 times greater than stated, or a total population size of 10,942,000 colonies, and an effective population size of 1,204,000 colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. speciosa*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. speciosa* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. speciosa*'s life history. Based on information from other *Acropora* species, *A. speciosa* is most likely a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. speciosa*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, and nutrients. The SRR and SIR did not provide any species-

specific information on the effects of these threats on *A. speciosa*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. speciosa*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide supplemental information on *A. speciosa*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora speciosa* has been rated as moderately or highly susceptible to bleaching and coral disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. speciosa* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. speciosa* likely is highly susceptible to ocean warming, and also likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. speciosa* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. speciosa*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. speciosa* occurs in 26 Indo-Pacific ecoregions that encompass 18 countries' EEZs. The 18 countries are Australia, Brunei, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Malaysia, Maldives, Marshall Islands, Palau, Papua New Guinea, Philippines, Solomon Islands, Taiwan, Timor-Leste, United States (PRIAs), and Vietnam. The regulatory mechanisms relevant to *A. speciosa*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (39 percent with none limited in scope), coral collection (67 percent with 28 percent limited in

scope), pollution control (50 percent with 17 percent limited in scope), fishing regulations on reefs (94 percent with 17 percent limited in scope), and managing areas for protection and conservation (100 percent with six percent limited in scope). The most common regulatory mechanisms in place for *A. speciosa* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also common for the species, but 28 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are less common regulatory mechanisms for the management of *A. speciosa*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *A. speciosa* include the relatively high susceptibility of the genus *Acropora* to common threats. It listed factors that reduce the threat of extinction for this species including high local abundance and broad depth range.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. speciosa*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the ecoregions in the Coral Triangle, the western Pacific, and the GBR, as well as parts of the Indian Ocean and central Pacific. Its geographic distribution moderates vulnerability to extinction

because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, so portions of the population in these areas will be less exposed to severe conditions. Its depth range of 12 to 40 moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters. However, while acidification is generally predicted to accelerate more quickly in waters that are deeper and cooler than those in which the species occurs, the lower portion of its depth range may be affected by acidification over the foreseeable future. Its habitat is lower reef slopes and walls, especially those characterized by clear water and high *Acropora* diversity on steep slopes. This specialized habitat may exacerbate vulnerability to extinction over the foreseeable future because the species is somewhat limited in its habitat, reducing the buffering capacity of habitat heterogeneity. While the geographic distribution, depth distribution, and habitat of *A. speciosa* all may moderate extinction risk over the foreseeable future, its effective population size of 1.2 million colonies substantially exacerbate extinction risk over the foreseeable future, because increasingly severe conditions are likely to affect a high proportion of its effective population at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. speciosa* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we maintain the species' proposed listing determination as threatened. Based on the best available information provided above on *A. speciosa*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora speciosa* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of

fishing (A), predation (C), and nutrient enrichment (A, E). These threats are expected to continue and increase into the future. In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D);

(2) Although *A. speciosa*'s habitat includes mesophotic depths which may provide some buffering capacity against threats that are more severe in shallower reef environments such as warming, its habitat is quite specialized, which may limit buffering capacity if threats are more pronounced within the type of habitat where the species occurs within; and

(3) *Acropora speciosa*'s effective population size of 1.2 million genetically distinct colonies could increase vulnerability to extinction if a high proportion of the effective population occurs within the parts of its range most affected by threats, potentially causing the species to decline to such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. speciosa*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) *Acropora speciosa* lives at depths of at least 40 m, providing some buffering capacity against threat-induced mortality events that may be more severe in shallow habitats; and

(2) *Acropora speciosa*'s total population size is estimated at 10.9 million colonies, approximately ten times the size of its effective population, providing a buffer against the species declining to such low abundance that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. speciosa*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora striata*

##### Introduction

The SRR and SIR provided the following information on *A. striata*'s morphology and taxonomy. Morphology was described as dense thickets with short cylindrical branches, and taxonomy was described as having no taxonomic issues but being similar in appearance to *A. tumida*, *A. sekesiensis*, and *A. parahemprichii*.

The public comments and information we gathered provided supplemental information on morphology or taxonomy. One public comment stated that specimens reported as *A. striata* in Guam differ in colony form and in other characteristics from the species described as *A. striata* in Veron (2000). We gathered supplemental information, including Wallace (1999b), which provide contradictory information to Veron (2000) regarding the morphology of this species. Veron (2014) states that *A. striata* is easily confused with other *Acropora* with a bushy growth form. Although there is uncertainty, we conclude that *A. striata* can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. striata*'s distribution, habitat, and depth range. *Acropora striata* is distributed from Indonesia to French Polynesia, and possibly to Japan. The species has the 54th largest range of 114 *Acropora* species. Its predominant habitat is upper reef slopes, and it occurs in other shallow habitats such as mid-slopes and lagoons, and its depth range is at 10 to 25 m.

The public comments did not provide any new or supplemental information on *A. striata*'s distribution. We gathered supplemental information, including Veron (2014), which reports that *A. striata* is confirmed in 36 of his 133

Indo-Pacific ecoregions, and strongly predicted to be found in an additional 17. Wallace (1999b) reports its occurrence in 16 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) estimated its range at 50 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. striata*'s habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. striata*'s abundance. *Acropora striata* has rare overall abundance but may be locally dominant in some areas in Japan.

The public comments did not provide any new or supplemental information on *A. striata*'s abundance. We gathered supplemental information, including Richards *et al.* (2013b), which concludes that this species is globally widespread, locally widespread, and locally rare. Veron (2014) reports that *A. striata* occupied 3.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.38 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "may be locally dominant in Japan, uncommon elsewhere." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. striata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi

*et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. striata* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years but a precise quantification is not possible due to the limited amount of species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *A. striata*'s life history. *Acropora striata* is a hermaphroditic spawner, with larval development and settlement taking five to 10 days, and larvae remaining competent for 31 days. The public comments and information we gathered did not provide anything additional to the above-described biological information.

##### Susceptibility to Threats

To describe *A. striata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. striata*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. striata*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. striata*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora striata* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). There is no species-specific information for the susceptibility of *A. striata* to any threat. Based on information from other *Acropora* species provided in the genus description above, *A. striata* is likely highly susceptible to ocean warming, and also likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation,

nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. striata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. striata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. striata* occurs in 36 Indo-Pacific ecoregions that encompass 38 countries' EEZs. The 38 countries are Australia, China, Comoros Islands, Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Japan, Jordan, Kenya, Kiribati, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, Nauru, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sudan, Taiwan, Tanzania, Thailand, Timor-Leste, Tonga, Tuvalu, United States (CNMI, Guam, American Samoa, PRIAs), and Vietnam. The regulatory mechanisms relevant to *A. striata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (26 percent with 3 percent limited in scope), coral collection (58 percent with 26 percent limited in scope), pollution control (45 percent with eight percent limited in scope), fishing regulations on reefs (89 percent with 21 percent limited in scope), and managing areas for protection and conservation (95 percent with eight percent limited in scope). The most common regulatory mechanisms in place for *A. striata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 26 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. striata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and

demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *A. striata* include its locally rare abundance. Factors that reduce the potential extinction risk *A. striata* include its relatively broad global distribution. Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. striata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from ten to 25 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower temperatures than surface waters due to local and micro-habitat variability in environmental conditions, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes, mid-slopes and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and

ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. striata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. striata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. striata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora striata*'s distribution across most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to

occur uniformly throughout the species range within the foreseeable future);

(2) *Acropora striata*'s total absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. striata* is not warranted for listing at this time under any of the listing factors.

#### *Acropora tenella*

##### Introduction

The SRR and SIR provided the following information on *A. tenella*'s morphology and taxonomy. Morphology was described as horizontal, platy colonies with flattened branches, and taxonomy was described as having no taxonomic issues but being similar in appearance to *Acropora pichoni*.

The public comments did not provide supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which states that *A. tenella* is readily confused with other flattened, finely branched *Acropora*.

However, the species is recognized as valid and distinct by experts (Veron, 2000; Wallace, 1999a), so we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. tenella*'s distribution, habitat, and depth range. *Acropora tenella* is distributed from Japan to Indonesia to New Guinea and the Marshall Islands. The species has the 43rd smallest range of 114 *Acropora* species. Its habitat is lower reef slopes and shelves between 40 and 70 meters, and it apparently is specialized for calm, deep conditions.

The public comments did not provide supplemental information on *A. tenella*'s distribution. We gathered supplemental information, including Veron (2014), which reports that *A. tenella* is confirmed in 18 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional six. Wallace (1999b) reports its occurrence in six of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) estimated its range at 15 million km<sup>2</sup>, which was the 43rd smallest range of 114 *Acropora* species examined. *Acropora tenella* was one of three species that dominated mesophotic reef habitat in Okinawa between 35 and 47 m depth (Sinniger *et al.*, 2013).

##### Demographic Information

The SRR and SIR provided the following information on *A. tenella*'s abundance. *Acropora tenella* has been reported as locally common in some locations.

The public comments did not provide supplemental information on *A. tenella*'s abundance. We gathered supplemental information, including Richards (2013b), which concludes that this species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction. Veron (2014) reports that *A. tenella* occupied 0.4 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.25 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare," and its overall abundance was also described as "rare." Veron did not infer trends in abundance from these data.

Richards *et al.* (2008) reported that *A. tenella* had the seventh lowest population of the 15 rare *Acropora* species they studied. Richards *et al.* (2008) gave the total world population of this species as about 5207 +/-1606 colonies, and the effective population size (*i.e.*, a mathematical estimate of the size of the breeding population) as about 573 colonies (Richards *et al.*, 2008). The calculation of the total world population of this species was flawed, since the area of 1 km<sup>2</sup> was given as 1,000 m<sup>2</sup> (Richards *et al.*, 2008: Appendix 1), when it is actually 1,000,000 m<sup>2</sup>. Thus, the correct population estimate is 1,000 times greater than stated, or a total population size of 5,207,000 colonies, and an effective population size of 573,000 colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. tenella*, the overall decline in abundance ("Percent Population Reduction") was estimated at 39 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. tenella* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *A. tenella*'s life history. Based on information from other *Acropora* species, *A. tenella* is most likely a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. The public comments and information we gathered did not provide anything additional to the above-described biological information.

### Susceptibility to Threats

To describe *A. tenella*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *A. tenella*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. tenella*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide supplemental information on *A. tenella*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora tenella* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. tenella* to any other threat. Based on information from other *Acropora* species provided in the genus description above, *A. tenella* is likely highly susceptible to ocean warming, and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. tenella* to the threats.

### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. tenella*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. tenella* occurs in 18 Indo-Pacific ecoregions that encompass 12 countries' EEZs. The 12 countries are Brunei, China, Federated States of Micronesia, Indonesia, Japan, Marshall Islands, Palau, Papua New Guinea, Philippines, Taiwan, United States (PRIAs), and Vietnam. The regulatory mechanisms relevant to *A. tenella*, described first as the percentage of the above countries

that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (25 percent with none limited in scope), coral collection (58 percent with 33 percent limited in scope), pollution control (33 percent with 17 percent limited in scope), fishing regulations on reefs (92 percent with 17 percent limited in scope), and managing areas for protection and conservation (100 percent with eight percent limited in scope). The most common regulatory mechanisms in place for *A. tenella* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat common for the species, but 33 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are much less prominent regulatory mechanisms for the management of *A. tenella*.

### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that one factor that reduces the potential extinction risk for this species is its deep depth range, which reduces exposure to surface-based threats. Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. tenella*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited to the Coral Triangle and parts of the western

equatorial Pacific Ocean. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its mesophotic depth range of 40 to 70 meters moderates vulnerability to extinction over the foreseeable future because of lower irradiance, sharply reducing warming-induced bleaching. In addition, other threats usually occur at lower levels at such depths, such as sedimentation resulting from land-based sources of pollution. However, unlike the other *Acropora* species in this final rule, *A. tenella*'s mesophotic habitat may often have substantially cooler temperatures than the shallower photic zone, and thus more likely to be affected by increasing acidification over the foreseeable future. Its habitat consists of lower reef slopes and shelves spanning 40 to 70 meters of depth, a much different habitat than the surface and shallow reef habitats occupied by the other *Acropora* species in this final rule. Its habitat may moderate vulnerability to extinction over the foreseeable future because of variable conditions at any given point in time. However, its habitat may exacerbate extinction risk over the foreseeable future because increasing acidification is expected to vary less spatially at these depths on coral reefs than in shallower areas on coral reefs. Its effective population size of approximately half a million colonies, combined with the location of its range, exacerbates vulnerability to extinction because increasingly severe conditions within the limited species range are likely to affect a high proportion of its effective population at any given point in time.

### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. tenella* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on moderate geographic distribution and wide depth distribution, E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we maintain the species' proposed listing determination as threatened. Based on the best available information provided above on *A. tenella*'s spatial structure,

demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Acropora tenella* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of fishing (A), predation (C), and nutrient enrichment (A, E). These threats are expected to continue and increase into the future. Although its mesophotic depth distribution may provide some buffering capacity against threats that are more severe in shallower reef environments, it may not provide buffering capacity against other threats for which depth is a less influential factor, like acidification and disease. In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D);

(2) *Acropora tenella*'s distribution is constrained mostly within the Coral Triangle and western equatorial Pacific, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. Although the mesophotic range of the species reduces the impacts of warming, disease, and localized human impacts, the species occurs at mesophotic depths where the effects of acidification are expected to be greater over the foreseeable future than in shallower areas; and

(3) *Acropora tenella*'s effective population size of 0.5 million colonies could increase vulnerability to extinction if a high proportion of the effective population occurs within the parts of its range most affected by threats, potentially causing the species to decline to such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. tenella*'s spatial structure, demography, threat susceptibilities, and management

also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *Acropora tenella*'s range is constrained to mesophotic habitat in the Coral Triangle and western Pacific, its habitat heterogeneity moderates vulnerability to extinction currently because of variable conditions at any given point in time. There is no evidence to suggest that the species is not so spatially fragmented or geographically constrained that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) *Acropora tenella*'s mesophotic depth distribution provides some buffering capacity against threats that are more severe in shallower environments such as nutrient enrichment, sedimentation, and ocean warming;

(3) *Acropora tenella*'s total population size is estimated at five million colonies, approximately ten times the size of its effective population, providing a buffer against the species declining to such low abundance that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time. Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. tenella*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Acropora vaughani*

##### Introduction

The SRR and SIR provided the following information on *A. vaughani*'s morphology and taxonomy. Morphology was described as open-branched, bushy, arborescent colonies, and the taxonomy was described as having no taxonomic issues but being similar to *A. horrida*, *A. tortuosa*, *A. rufus* and *A. austra*.

The public comments did not provide supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which indicates that *A. vaughani* is distinctive, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. vaughani*'s distribution, habitat, and depth range. *Acropora vaughani* is distributed from the Red Sea to Fiji. The species has the 34th largest range of 114 *Acropora* species. It is found in numerous reef slope and back-reef habitats with turbid water, including but not limited to, upper reef slopes, mid-slope terraces, lagoons, and adjacent habitats, and the depth range is from low tide to 20 or 30 meters.

The public comments did not provide supplemental information on *A. vaughani*'s distribution. We gathered supplemental information, including Veron (2014), who reports that *A. vaughani* is confirmed in 59 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 13. Wallace (1999b) reports its occurrence in 24 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. vaughani* at over 80 million km<sup>2</sup>. The public comments and information we gathered provided nothing additional on *A. vaughani*'s habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *A. vaughani*'s abundance. *Acropora vaughani* is reported to be uncommon. The public comments did not provide supplemental information on *A. vaughani*'s abundance. We gathered supplemental information, including Richards *et al.* (2013b), which conclude from their data that this species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category of *Acropora* with the predicted consequence of local extinction. Veron (2014) reports that *A. vaughani* occupied 7.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.69 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was

described as “uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. vaughani*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. vaughani* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. vaughani*'s life history. *Acropora vaughani* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae. It is one of several *Acropora* that achieve reproductive isolation by spawning earlier in the evening than other species. The public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. vaughani*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection

and trade. The SRR and SIR also provided species-specific information reporting that *Acropora* species including *A. vaughani* suffered greater than 90 percent mortality during the 1996 and 1998 bleaching events in the southeastern Arabian Gulf, but that portions of some *A. vaughani* survived, contributing to potentially accelerated recovery. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. vaughani*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. vaughani*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments provided some supplemental information on *A. vaughani*'s threat susceptibilities. One comment stated that *A. vaughani* is more susceptible to predation than indicated in the proposed rule because of the overlap in the depth ranges of this species with crown of thorns starfish. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora vaughani* has been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). All *Acropora* species in the southeastern Arabian Gulf, including *A. vaughani*, suffered nearly complete mortality during the 1996 bleaching event (Riegl, 1999), but some *A. vaughani* colonies survived the 1998 mass bleaching event (Riegl and Piller, 2001). No other species-specific information is available for the susceptibility of *A. vaughani* to any other threat. For the other threats, based on information from other *Acropora* species provided in the genus description above, *A. vaughani* may be susceptible to the effects of coral disease, ocean acidification, predation, sedimentation, nutrient enrichment, trophic effects of fishing, sea-level rise, and collection and trade. Thus, based on the available species-specific and genus information summarized above, *A. vaughani* is likely highly susceptible to ocean warming, and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the

susceptibilities of *A. vaughani* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. vaughani*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. vaughani* occurs in 59 Indo-Pacific ecoregions that encompass 43 countries' EEZs. The 43 countries are Australia, Cambodia, China, Comoros Islands, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Israel, Japan, Jordan, Kenya, Kiribati, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan, Taiwan, Tanzania, Thailand, Timor-Leste, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (CNMI, Guam, American Samoa, PRIAs), Vietnam, and Yemen. The regulatory mechanisms relevant to *A. vaughani*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (28 percent with five percent limited in scope), coral collection (58 percent with 26 percent limited in scope), pollution control (44 percent with seven percent limited in scope), fishing regulations on reefs (91 percent with 19 percent limited in scope), and managing areas for protection and conservation (95 percent with nine percent limited in scope). The most common regulatory mechanisms in place for *A. vaughani* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 26 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. vaughani*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat

susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that reduce the potential extinction risk for this species include the broad global distribution, the wide range of habitats occupied by *A. vaughani*, its use in restoration and replantation, and its known recovery after bleaching events via tissue remnants from within the reef framework.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. vaughani*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes about half of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to 20 or 30 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes turbid upper reef slopes, mid-slope terraces, lagoons, and adjacent habitats, and the depth range is from low tide to 20 or 30 meters. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and

regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. vaughani* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. vaughani* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. vaughani*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora vaughani*'s distribution is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not

identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora vaughani*'s total abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. vaughani* is not warranted for listing at this time under any of the listing factors.

#### *Acropora verweyi*

##### Introduction

The SRR and SIR provided the following information on *A. verweyi*'s morphology and taxonomy. Morphology was described as clumps with noticeably rounded or bulb-like corallites, and taxonomy was described as having no taxonomic issues.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014) which states that *A. verweyi* is distinctive, thus we conclude it can be identified by experts

and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. verweyi*'s distribution, habitat, and depth range. *Acropora verweyi* is distributed from the western Indian Ocean to the central Pacific. The species has the 16th largest range of 114 *Acropora* species. Its habitat is predominantly lower reef crests, upper reef slopes and other high energy habitats and its depth range is to at least 15 m.

The public comments did not provide any new or supplemental information on *A. verweyi*'s distribution. We gathered supplemental information, including Veron (2014), which reports that *A. verweyi* is confirmed in 63 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 17. Wallace (1999b) reports it from 17 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) calculated the geographic range of *A. verweyi* at over 100 million km<sup>2</sup>. *Acropora verweyi* occurs in many different habitats, including fringing reefs with turbid water (Veron, 2000), and shallow reef top and reef edge habitats (Wallace, 1999b). *Acropora verweyi* occurs on upper reef slopes, especially those exposed to wave action or currents (Veron, 2014). Carpenter *et al.* (2008) give the depth range for *A. verweyi* as 2 to 15 meters.

#### Demographic Information

The SRR and SIR provided the following information on *A. verweyi*'s abundance. *Acropora verweyi* is generally common, but can be locally abundant, especially in the western Indian Ocean. The public comments did not provide any new or supplemental information on *A. verweyi*'s abundance. We gathered supplemental information, including Richards *et al.* (2013b), which concludes that the species is globally widespread, locally widespread, and locally rare. Veron (2014) reports that *A. verweyi* occupied 4.7 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.59 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "occasionally common in the western Indian Ocean." Veron did not infer trends in abundance from these data. As described in the Indo-

Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. verweyi*, the overall decline in abundance ("Percent Population Reduction") was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. verweyi* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible.

#### Other Biological Information

The SRR and SIR provided the following information on *A. verweyi*'s life history. *Acropora verweyi* is a hermaphroditic spawner that is a participant in mass broadcast spawning in some localities. The public comments and information we gathered did not provide anything additional to the above-described biological information based on the limited species-specific information.

#### Susceptibility to Threats

To describe *A. verweyi*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. verweyi*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the

proposed rule for *A. verweyi*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, nutrients, and predation, and low vulnerabilities to sedimentation, sea-level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. verweyi*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Acropora verweyi* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). *Acropora verweyi* tolerates high temperatures in back-reef pools on Ofu, American Samoa where corals are more tolerant than elsewhere due to repeated brief exposure to high temperatures (Craig *et al.*, 2001), although *A. verweyi* is not abundant and acroporids still bleach some in these pools (Fenner and Heron, 2008). *Acropora verweyi* was relatively resistant to bleaching in Moorea during the 1991 warming event (Gleason, 1993). Reduced carbonate concentrations decrease calcification rates in *A. verweyi* (Marubini *et al.*, 2003). While the overall magnitude of calcification was similar to the other coral species tested, *A. verweyi* showed reductions in mineral density that other species did not, potentially making it more susceptible to bioerosion or breaking from wave action (Marubini *et al.*, 2003). No other species-specific information is available for the susceptibility of *A. verweyi* to any other threat. For the other threats, based on information from other *Acropora* species provided in the genus description above, *A. verweyi* may be susceptible to the effects of disease, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. Thus, based on the available species-specific and genus information summarized above, *A. verweyi* is likely to have some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. verweyi* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. verweyi*. Criticisms of our approach

received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. verweyi* occurs in 63 Indo-Pacific ecoregions that encompass 41 countries' EEZs. The 41 countries are Australia, Cambodia, China, Comoros Islands, Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Japan, Jordan, Kenya, Kiribati, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, Nauru, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan, Taiwan, Tanzania, Thailand, Tonga, Tuvalu, United Kingdom (Pitcairn Islands), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *A. verweyi*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (27 percent with seven percent limited in scope), coral collection (56 percent with 29 percent limited in scope), pollution control (44 percent with seven percent limited in scope), fishing regulations on reefs (90 percent with 22 percent limited in scope), and managing areas for protection and conservation (95 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. verweyi* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. verweyi*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that the factors that increase the potential extinction risk for *A. verweyi* include the relatively high susceptibility of the genus *Acropora* to common threats. It listed factors that reduce the potential extinction risk for *A. verweyi* including its very wide latitudinal and

longitudinal geographic range, observations of occasional resistance to thermal stress in shallow backreef pools, and its relatively common abundance.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. verweyi*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to at least 15 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes lower reef crests, upper reef slopes and other high energy habitats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly

variable thermal regimes and ocean chemistry at any given point in time. In addition, areas with good circulation experience high levels of mixing which can dilute adverse environmental conditions. Its absolute abundance of at least tens to hundreds of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. verweyi* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. verweyi* from threatened to not warranted. No supplemental information or public comments changed our assessment of the type and severity of threats affecting *A. verweyi*. Rather, we made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. verweyi*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acropora verweyi*'s distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central

Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Acropora verweyi*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Despite its current distribution, *A. verweyi* is characterized as uncommon overall, thus its abundance may not provide much buffering capacity in terms of overall numbers. In addition, *A. verweyi* showed reductions in mineral density in response to reduced carbonate concentrations, potentially making it more susceptible to bioerosion or breaking from wave action as ocean acidification increases. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of its range to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A.*

*verweyi* is not warranted for listing at this time under any of the listing factors.

#### Genus *Anacropora*

##### Genus Introduction

The family Acroporidae includes five genera, *Acropora*, *Montipora*, *Astreopora*, *Isopora*, and *Anacropora*. *Anacropora* contains seven species, all occurring in the Indo-Pacific. Like most *Acropora* species, colonies of *Anacropora* species are branching. Unlike *Acropora*, there is no corallite on the tip of the branches of *Anacropora* colonies, a diagnostic characteristic of *Acropora* (Veron, 2000). *Anacropora* is morphologically like branching *Montipora* without an encrusting base (Veron and Wallace, 1985). The SRR and SIR provided the following genus-level introductory information on *Anacropora*. Morphologic taxonomy has been unable to resolve whether *Anacropora* are recently derived from *Montipora* or from *Acropora*, but genetic evidence supports the former view.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Anacropora*. The bleaching susceptibility in the genus *Anacropora* is not well known. In the 1998 bleaching event in Palau, *Anacropora* colonies (not identified to species) were moderately affected relative to other coral genera, with total mortality of some *Anacropora* colonies in some limited areas, while those in other areas were unaffected. This was a major bleaching event, with 48 percent bleaching overall (all coral species combined), and bleaching and mortality of different genera and species ranging from zero to nearly 100 percent (Bruno *et al.*, 2001). With regard to predation, *A. puertogalerae* have been reported to be only preyed on by wrasses in proportion to its availability (Cole *et al.*, 2010). With regard to sedimentation and nutrients, some *Anacropora* species appear resistant to both these threats while others appear susceptible (Mohammed and Mohammed, 2005). Collection and trade in the genus *Anacropora* has been reported to be negligible, with only 14 pieces reported in export over the last decade (CITES, 2010).

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Anacropora*. We gathered supplemental information that provided the following. One study reported that disease was not found on *Anacropora* at a site in Indonesia, while the taxon with

the highest prevalence out of 25 taxa had 8 percent prevalence of disease (Haapkyla *et al.*, 2007).

##### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and information we gathered, we can make the following inferences about the susceptibilities of an unstudied *Anacropora* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as "high" importance, and ocean acidification as "medium-high" importance, to corals. These were rated as the three most important threats to reef-building corals overall. The one available study on the effects of ocean warming on *Anacropora* reported variable thermal-induced bleaching within the genus (Bruno *et al.*, 2001). While there is no other genus-level or species-specific information on the susceptibilities of *Anacropora* species to ocean warming, the SRR rated it as "high" importance to corals. Thus, we conclude that an unstudied *Anacropora* species has some susceptibility to ocean warming. Similarly for ocean acidification, while there is no genus-level or species-specific information on the susceptibilities of *Anacropora* species to ocean acidification, the SRR rated it as "medium-high" importance to corals. Thus, we conclude that an unstudied *Anacropora* species has some susceptibility to ocean acidification. The one available study on the effects of disease on *Anacropora* reported no disease on *Anacropora* colonies (Haapkyla *et al.*, 2007). However, this single study is inadequate to imply susceptibility level for all *Anacropora* species, thus we conclude that *Anacropora* has some susceptibility to disease.

The SRR rated the trophic effects of fishing as "medium" importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Anacropora* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. The one available study on the effects of sedimentation and nutrients (Mohammed and Mohammed, 2005) on *Anacropora* species suggest either intermediate or variable susceptibilities. Thus we conclude that an unstudied *Anacropora* species has some susceptibility to sedimentation and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Anacropora* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. The one available study on the effects of predation (Cole *et al.*, 2010) on *Anacropora* species suggest either intermediate or variable susceptibility, thus we conclude that an unstudied *Anacropora* species has some susceptibility to predation. Because the available information suggests that *Anacropora* species are lightly collected and traded, an unstudied *Anacropora* species is likely to have low susceptibility to collection and trade.

In conclusion, an unstudied *Anacropora* species is likely to have some susceptibility to ocean warming, disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and low susceptibility to collection and trade.

#### *Anacropora puertogalerae*

##### Introduction

The SRR and SIR provided the following information on *A. puertogalerae*'s morphology and taxonomy. Morphology was described as compact branches, typically less than 13 mm in diameter and tapering, with thin spines under corallites, and taxonomy was described as having no taxonomic issues but being similar in appearance to *A. spinosa* and *A. forbesi*.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. puertogalerae*, but that there is a moderate level of species identification uncertainty for this species. However, the species can be identified by experts (Fenner, 2014b), thus we conclude that the distribution and abundance

information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. puertogalerae*'s distribution, habitat, and depth range. *Anacropora puertogalerae*'s distribution is the Coral Triangle and western equatorial Pacific, plus southern Japan to the GBR. Its habitat includes both coral reef and non-reef environments, including upper reef slopes, mid-slopes, and lagoons on reefs, and various substrates in non-reef areas. Its depth range as five to at least 20 meters depth.

The public comments did not provide any new or supplemental information on *A. puertogalerae*'s distribution. We gathered supplemental information, including Veron (2014), which reports that *A. puertogalerae* is confirmed in 26 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional seven.

##### Demographic Information

The SRR and SIR provided the following information on *A. puertogalerae*'s abundance. *Anacropora puertogalerae* is reported to be uncommon but can form large thickets in the Philippines.

The public comments did not provide any new or supplemental information on *A. puertogalerae*'s abundance. We gathered supplemental information, including Veron (2014), which states that it is sometimes a dominant species where it occurs. Veron (2014) reports that *A. puertogalerae* occupied 4.6 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 2.02 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “uncommon.” Overall abundance was also described as “uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. puertogalerae*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 38 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population

Reduction”) was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. puertogalerae* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *A. puertogalerae*'s life history. *Anacropora puertogalerae* has been reported to be a simultaneous hermaphrodite and a broadcast spawner. Clonal structure suggests the species also reproduces by fragmentation. Larvae contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments and information we gathered provided no additional biological information.

##### Susceptibility to Threats

To describe *A. puertogalerae*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR provided the following species-specific information on *A. puertogalerae*'s threats. In a two month study in Kimbe Bay, PNG, it was observed that *A. puertogalerae* was only preyed on by wrasses in proportion to its availability (Cole *et al.*, 2010). The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. puertogalerae*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. puertogalerae*'s vulnerabilities as follows: High vulnerability to ocean

warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, nutrients and predation, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *A. puertogalerae*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Anacropora puertogalerae* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on the genus and species-specific information described above, *A. puertogalerae* likely has some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, and predation, and low susceptibility to collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. puertogalerae* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. puertogalerae*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. puertogalerae* occurs in 26 Indo-Pacific ecoregions that encompass 16 countries' EEZs. The 16 countries are Australia, Brunei, China, Fiji, France (French Pacific Island Territories), Indonesia, Japan, Malaysia, Palau, Papua New Guinea, Philippines, Solomon Islands, Taiwan, Timor-Leste, Vanuatu, and Vietnam. The regulatory mechanisms relevant to *A. puertogalerae*, described first as the percentage of the above countries that utilize them, to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (38 percent with 6 percent limited in scope), coral collection (69 percent with 38 percent limited in scope), pollution control (44 percent with 19 percent limited in scope), fishing regulations on reefs (100 percent with 19 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *A. puertogalerae* are reef fishing

regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 38 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. puertogalerae*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that "factors that increase the potential extinction risk for *A. puertogalerae* are that the high susceptibility to threats common to members of the genus *Acropora* (bleaching, disease, and predation) are generally considered appropriate to species in the confamilial genus *Anacropora* as well." It noted that a factor that reduces potential extinction risk is that *A. puertogalerae* has a somewhat broad range.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. puertogalerae*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many of the coral reef ecoregions in the western and central Pacific Ocean; the Coral Triangle and western equatorial Pacific, plus southern Japan to the GBR. On one hand, this moderates vulnerability to extinction because the high latitude areas in the northern and southern portions of its range are projected to have less than average warming over the foreseeable future, thus populations in these areas will be less exposed to

severe warming conditions. On the other hand, the species' geographic distribution exacerbates vulnerability to extinction because much of it lies within the western equatorial Pacific, an area projected to have the highest seawater temperatures in the foreseeable future. Its depth range is from five to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes both coral reef and non-reefal environments, including upper reef slopes, mid-slopes, and lagoons on reefs, and various substrates in non-reefal areas. This is particularly important for moderating vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef and non-reefal environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. puertogalerae* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. puertogalerae* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic

traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. puertogalerae*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Anacropora puertogalerae*'s distribution is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming, including high latitude areas in both the northern and southern portions of the species' range. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Anacropora puertogalerae* occurs in very diverse habitats, including both coral reef and non-reefal habitats so the species will experience a variety of environmental conditions at any given time; and

(3) *Anacropora puertogalerae*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to

moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future. Therefore, *A. puertogalerae* is not warranted for listing at this time under any of the listing factors.

#### *Anacropora spinosa*

##### Introduction

The SRR and SIR provided the following information on *A. spinosa*'s morphology and taxonomy. Morphology was described as compact branches, less than 10 mm in diameter and tapering. They have elongate, crowded, irregular spines that are not strongly tapered, and taxonomy was described as having no taxonomic issues but being similar in appearance to *Anacropora puertogalerae*.

The public comments and information we gathered did not provide information on morphology, and confirmed that there are no known taxonomic problems for *A. spinosa* and that there is a moderate level of species identification uncertainty for this species. Veron (2014) states that *A. spinosa* is easily confused with *Anacropora puertogalerae*. However, the species can be identified by experts (Fenner, 2014b), thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. spinosa*'s distribution, habitat, and depth range. *Anacropora spinosa*'s distribution is the Coral Triangle and southern Japan. Its habitat includes both coral reef and non-reefal environments, including upper reef slopes, mid-slopes, and lagoons on reefs, and various substrates in non-reefal areas. Its depth range is five to 15 meters deep.

The public comments provided the following information that a photograph of *A. spinosa* that appeared in Veron (2000) was erroneously attributed to Guam but was actually taken in Palau. We gathered supplemental information, including Veron (2014), which reports that *A. spinosa* is confirmed in 13 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional six.

##### Demographic Information

The SRR and SIR provided the following information on *A. spinosa*'s abundance. Its abundance is reported to be uncommon, but it may occur in extensive tracts in certain areas.

The public comments did not provide any new or supplemental information on *A. spinosa*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. spinosa* occupied 1.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.84 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was described as "usually uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. spinosa*, the overall decline in abundance ("Percent Population Reduction") was estimated at 58 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 22 percent in the study. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by harder coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. spinosa* occurs in many areas affected by these broad changes, and that it has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

## Other Biological Information

The SRR and SIR provided the following information on *A. spinosa*'s life history: *Anacropora spinosa* has been reported to be a simultaneous hermaphrodite that broadcast spawns mature gametes. Planula larvae contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments and information we gathered did not provide anything additional to the above-described biological information.

## Susceptibility to Threats

To describe *A. spinosa*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Anacropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR provided the following species-specific information on *A. spinosa*'s threats. The only known export of *A. spinosa* was a single specimen from Indonesia in 2005. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. spinosa*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, nutrients, and predation, and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *A. spinosa*'s threat susceptibilities, but we gathered species-specific and genus-level supplemental information on this species' threat exposures. *Anacropora spinosa* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. spinosa* to any other threat.

Based on information provided in the genus description above, *A. spinosa* likely has some susceptibilities to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and low susceptibility to collection and trade. The available information does not support more precise ratings of the susceptibilities of *A. spinosa* to the threats.

## Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for

*A. spinosa*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. spinosa* occurs in 13 Indo-Pacific ecoregions that encompass six countries' EEZs. The six countries are Indonesia, Japan, Palau, Papua New Guinea, Philippines, and the Solomon Islands. The regulatory mechanisms relevant to *A. spinosa*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (17 percent with none limited in scope), coral collection (67 percent with 33 percent limited in scope), pollution control (17 percent with 17 percent limited in scope), fishing regulations on reefs (100 percent with none limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *A. spinosa* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat common for the species, but 33 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *A. spinosa*.

## Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated factors that increase the potential extinction risk for *A. spinosa* are that the high susceptibility to threats common to members of the genus *Acropora* (bleaching, disease, and predation) are generally considered appropriate to species in the confamilial genus *Anacropora* as well.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the

species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. spinosa*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited to the Coral Triangle and southern Japan. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range is five to 15 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes upper reef slopes, mid-slopes, and lagoons on reefs, and various substrates in non-reefal areas. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef and non-reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. There is not enough information about its abundance to determine if it moderates or exacerbates extinction: It is uncommon and has at least millions of colonies, but the great majority of the population is within an area expected to be severely impacted by threats over the foreseeable future.

## Listing Determination

In the proposed rule using the determination tool formula approach, *A. spinosa* was proposed for listing as endangered because of: High vulnerability to ocean warming (ESA

Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. spinosa* from endangered to threatened. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information provided above on *A. spinosa*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Anacropora spinosa* is likely to be susceptible to ocean warming (ESA Factor E), disease (C), ocean acidification (E), trophic effects of fishing (A), nutrients (A, E), and predation (C). In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D); and

(2) *Anacropora spinosa*'s distribution is constrained almost entirely within the Coral Triangle, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *A. spinosa*'s spatial structure, demography, threat susceptibilities, and management

also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *A. spinosa*'s distribution is constrained almost entirely to the Coral Triangle which increases its extinction risk as described above, its habitat includes shallow reef environments, generally in clear or slightly turbid water and on soft substrates of lower reef slopes, and it has also been found in non-reef environments. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef and non-reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) *Anacropora spinosa*'s absolute abundance is at least millions of colonies which allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *A. spinosa*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the

species status to the point at which listing is not warranted.

#### Genus *Astreopora*

##### Genus Introduction

The family Acroporidae includes five genera, *Acropora*, *Montipora*, *Astreopora*, *Isopora*, and *Anacropora*. *Astreopora* contains 15 species, all occurring in the Indo-Pacific (Veron, 2000; Wallace *et al.*, 2011). Unlike *Acropora* and *Anacropora* species, *Astreopora* colonies are massive, laminar, or encrusting. The SRR and SIR provided no genus-level introductory information on *Astreopora*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Astreopora*. *Astreopora* species can be susceptible to bleaching, although overall *Astreopora* species are less susceptible to bleaching than other genera within the family Acroporidae, and often survive when they do bleach. Congeners have contracted a fungal disease in Kenya, and *Astreopora myriophthalma* was infected with black-band disease at a polluted site in Jordan. Trade in the genus *Astreopora* has been reported to be light and sporadic.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Astreopora*, but the supplemental information provided the following. In Palau in 1998, *Astreopora* species had moderate levels of bleaching and moderate mortality (Bruno *et al.*, 2001). In Kenya in 1998, three quarters of *Astreopora* species within marine protected areas were affected by mass bleaching. Although many *Astreopora* colonies bleached, none died. Of the 18 genera included in the study, five genera including *Astreopora* had some bleaching but no mortality, and the bleaching index for *Astreopora* was the fifth lowest of the 18 genera (McClanahan *et al.*, 2004; McClanahan *et al.*, 2001). In Thailand in 1998 and 2010, all colonies of *Astreopora myriophthalma* completely bleached, but in both events, all colonies completely recovered (Sutthacheep *et al.*, 2013). In Mauritius in 2004, the *Astreopora* genus had the 23rd highest bleaching rate of the 32 genera recorded, and 12 percent of the highest value (McClanahan *et al.*, 2005a). In eight countries in the western Indian Ocean in 1998–2005, the *Astreopora* genus had the 21st highest bleaching rate of the 45 genera recorded, and 39 percent of the highest value (McClanahan *et al.*, 2007a).

On the GBR, *Astreopora* species had a very low level of Black Band Disease occurrence, just two percent the level of this disease found in *Acropora* species at the same sites (Page and Willis, 2006). Likewise, another study from the GBR reported that *Astreopora* species had low susceptibility to Skeletal Eroding Band, with a prevalence of 0.1 percent. Skeletal Eroding Band is the most prevalent coral disease on the GBR (Page and Willis, 2007). In New Caledonia, *Astreopora* was reported to have a disease prevalence of 0.5 percent, which was the fifth highest prevalence of 12 genera reported (Tribollet *et al.*, 2011). In Indonesia, *Astreopora* had a disease prevalence of 1.5 percent, which was the 2nd highest reported among 35 taxa (Haapkyla *et al.*, 2007).

In a study of sediment rejection in 22 coral species (including one *Astreopora* species), *A. myriophthalma* cleared 98 percent of the sediment within 48 hours, the seventh most efficient of the 22 species at clearing sediment (Stafford-Smith, 1993). *Astreopora* species trade has been reported to be light and sporadic (CITES, 2010). There is no information available on the effects of any other threat for *Astreopora* species.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Astreopora* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. The studies cited above on thermal stress in *Astreopora* report moderate levels of bleaching in response to warming events, but low mortality levels. The studies cited above report variable levels of disease in *Astreopora*. Thus, we conclude that *Astreopora* has some susceptibility to ocean warming and disease. Although there is no genus-level or species-specific information on the susceptibilities of *Astreopora* species to ocean acidification, the SRR rated it as “medium-high” importance to corals. Thus, we conclude that an unstudied *Astreopora* species has some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at

the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Astreopora* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. The study cited above reports high sediment rejection efficiency in *A. myriophthalma*. This one study is inadequate to rate the susceptibility as low, thus we conclude that *Astreopora* has some susceptibility to sedimentation. Although there is no genus-level or species-specific information on the susceptibilities of *Astreopora* species to nutrients, the SRR rated it as “low-medium” importance to corals. Thus, we conclude that an unstudied *Astreopora* species has some susceptibility to nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Astreopora* species is likely to have some susceptibility to sea-level rise. Although there is no genus-level or species-specific information on the susceptibilities of *Astreopora* species to predation, there is no information suggesting they are not susceptible to these threats. Thus, we conclude that an unstudied *Astreopora* species has some susceptibility to predation. The SRR rated ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. Although there is no other genus-level or species-specific information on the susceptibilities of *Astreopora* species to collection and trade, there is no information suggesting they are not susceptible to these threats. Thus we conclude that an unstudied *Astreopora* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Astreopora* species is likely to have some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

## *Astreopora cucullata*

### Introduction

The SRR and SIR provided the following information on *A. cucullata*'s morphology and taxonomy. Morphology was described as thick or encrusting platy colonies, with inclined corallites, and taxonomy was described as having no taxonomic issues but being similar to *Astreopora scabra*.

The public comments and information we gathered did not provide information on morphology, and confirmed that there are no known taxonomic problems for *A. cucullata*, but that there is a high level of species identification uncertainty for this species. Veron (Veron, 2014) states that *A. cucullata* is not readily distinguished from other *Astreopora* but Veron (Lamberts, 1980; Lamberts, 1982; Veron, 2000) considers it a valid species, thus we conclude it is sufficiently distinctive to be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

### Spatial Information

The SRR and SIR provided the following information on *A. cucullata*'s distribution, habitat, and depth range. *Astreopora cucullata*'s distribution is a broad distribution, from the Red Sea and central Indo-Pacific to the central Pacific. The SRR and SIR described *A. cucullata*'s habitat as protected reef environments, and the depth range as five to 15 m. The public comments provided the following information. One comment stated that *A. cucullata* was recorded from Apra Harbor, Guam, but no sample or photo was provided for confirmation. We gathered supplemental information, including Veron (2014), which reports that *A. cucullata* is confirmed in 31 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 15. *Astreopora cucullata* occurs in most reef environments except reef flats (Lamberts, 1980; Lamberts, 1982; Veron, 2000). It has been reported as “found only in deep waters at reef edges” (Lamberts, 1980), and is likely to have a depth range of approximately 3 m to at least 20 m. Fenner (personal comm.) reports it is on outer reef slopes in American Samoa. Thus, based on all the available information, *A. cucullata*'s habitat includes most coral reef habitats, including at least upper reef slopes, mid-slope terraces, lower reef slopes, lower reef crests, and lagoons in depths ranging from two to 20 m depth.

### Demographic Information

The SRR and SIR provided the following information on *A. cucullata*'s abundance. *Astreopora cucullata* is reported as rare. The SIR reported it is common in parts of its range such as in American Samoa (Fenner *et al.*, 2008) and Guam (Lamberts, 1982). *Astreopora cucullata* was found in 10 of 51 sites (Donnelly *et al.*, 2003) and four of 39 sites (Turak and DeVantier, 2003) in Indonesian national park surveys.

The public comments did not provide any new or supplemental information on *A. cucullata*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. cucullata* occupied 6.8 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.25 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was described as "rare." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. cucullata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 34 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 13 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. cucullata* occurs in many areas affected by these broad changes, and has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the

past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

### Other Biological Information

The SRR and SIR provided the following information on *A. cucullata*'s life history. Reproductive characteristics of *A. cucullata* have not been determined. However, other species in the *Astreopora* genus (*Astreopora gracilis*, *Astreopora myriophthalma*, and *Astreopora listeri*) are hermaphroditic broadcast spawners. The public comments and information we gathered provided no additional biological information.

### Susceptibility to Threats

To describe *A. cucullata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Astreopora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR provided the following species-specific information on *A. cucullata*'s threats. A single *A. cucullata* export was reported from Saudi Arabia in 1999. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. cucullata*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. cucullata*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *A. cucullata*'s threats, but we gathered species-specific and genus-level supplemental information on this species' threat exposures, susceptibilities, and vulnerabilities. *Astreopora cucullata* has been rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). No other species-specific information is available for the susceptibility of *A. cucullata* to any other threat. Based on the available genus-level and species information summarized above, *A. cucullata* likely has some susceptibilities to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, predation, sea-level rise, and collection and trade. The available information does not support more precise ratings of susceptibilities of *A. cucullata* to the threats.

### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. cucullata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *A. cucullata* occurs in 31 Indo-Pacific ecoregions that encompass 30 countries' EEZs. The 30 countries are Australia, Brunei, China, Djibouti, Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Jordan, Malaysia, Marshall Islands, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Sudan, Thailand, Timor-Leste, Tonga, Tuvalu, United States (American Samoa, Guam), Vietnam, and Yemen. The regulatory mechanisms relevant to *A. cucullata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (23 percent with 0 percent limited in scope), coral collection (67 percent with 30 percent limited in scope), pollution control (50 percent with 10 percent limited in scope), fishing regulations on reefs (87 percent with 17 percent limited in scope), and managing areas for protection and conservation (97 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. cucullata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 30 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. cucullata*.

### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *A. cucullata* are its rarity and that it belongs to a family that is highly susceptible to stress. It listed factors that reduce the potential

extinction risk including a widespread distribution and the fact that it appears to be less vulnerable to bleaching than other species in its family.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. cucullata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes the Red Sea, parts of the western Indian Ocean, and most of the ecoregions throughout the western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from two to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slope terraces, lower reef slopes, lower reef crests, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction

because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. cucullata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. cucullata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. cucullata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Astreopora cucullata*'s distribution in the Red Sea, central Indo-Pacific, and the central Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) While *A. cucullata*'s qualitative abundance is characterized as rare, its absolute abundance at least tens of millions of colonies, providing buffering

capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. cucullata* is not warranted for listing at this time under any of the listing factors.

#### *Genus Isopora*

##### Genus Introduction

The family Acroporidae includes five genera, *Acropora*, *Montipora*, *Astreopora*, *Isopora*, and *Anacropora*. *Isopora* was formerly considered a sub-genus of *Acropora*, but was recently elevated to genus level (Wallace *et al.*, 2007). The genus contains seven species, all occurring in the Indo-Pacific. *Isopora* have branching or encrusting colonies. The SRR and SIR provided no genus-level introductory information on *Isopora*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Isopora*. *Isopora cuneata* has intermediate bleaching susceptibility relative to other acroporids but showed severe losses in a 2006 mass bleaching event in the Marshall Islands, with only shaded bases of colonies surviving. *Isopora cuneata* was a common species in the

*Acropora palifera* zone of the Chagos, but *I. cuneata* was nearly completely eliminated in 1998 and has not yet regenerated. Competition with algae significantly reduces growth rates of *I. cuneata*. At high latitude Lord Howe Island, *I. cuneata* was found to host five types of C zooxanthellae, with an ability to host specialized types in turbid environments. The species is also capable of photo-adapting to low light environments by increasing zooxanthellae density altering photosynthetic mechanisms (dark reaction enzymes or electron transport rates).

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Isopora*. We gathered supplemental information that provided the following material. A large study of the bleaching responses of over 100 coral species on the GBR to the 2002 bleaching event included three *Isopora* species (Done *et al.*, 2003b). At that time, *Isopora* species were still considered *Acropora* species, and they are listed in the report as *Acropora palifera*, *A. cuneata*, and *A. brueggemanni*, but these three species are now referred to as *Isopora palifera*, *I. cuneata*, and *I. brueggemanni*. For *I. palifera*, approximately 42 percent of the observed colonies were bleached, resulting in *I. palifera* being more affected than 43 of the 45 *Acropora* species in the study, and one of the 20 most affected species in the study. For *I. cuneata* and *I. brueggemanni*, approximately 20 percent of the observed colonies for both species were bleached, an intermediate bleaching level compared to the 45 *Acropora* species in the study (Done *et al.*, 2003b). In response to a 2008 bleaching event in Papua New Guinea, two Pocilloporidae and 14 Acroporidae species (including *I. brueggemanni*) were monitored: five of the 16 species had severe or high “relative susceptibility” to bleaching, (including *I. brueggemanni*, which was rated as high). All 29 *I. brueggemanni* colonies were bleached severely, but none were killed (Bonin, 2012).

In a study of coral disease on the GBR, approximately one percent of colonies of observed *Isopora* were affected by Skeletal Eroding Band, the most prevalent coral disease on the GBR (Page and Willis, 2007). *Isopora* had a disease prevalence of 1% in Indonesia, which was tied for 5th highest among 35 taxa (Haapkyla *et al.*, 2007). *Isopora crateriformis* and *I. palifera* were affected differently by white diseases in American Samoa: an outbreak resulted in low prevalence in *I. crateriformis*, but high prevalence in *I. palifera* (D. Fenner,

personal comm.). There is no information available on the effects of any other threat for *Isopora* species.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Isopora* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. The studies described above report moderate to high levels of bleaching in *Isopora* species in response to warming events. With regard to disease, the information above indicates variable levels (from low to high) of disease in *Isopora* species. Thus, we conclude that *Isopora* is likely to be highly susceptible to ocean warming and to have some susceptibility to disease. Although there is no genus-level or species-specific information on the susceptibilities of *Isopora* species to ocean acidification, the SRR rated it as “medium-high” importance to corals. Thus, we conclude that an unstudied *Isopora* species has some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Isopora* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. Although there is no genus-level or species-specific information on the susceptibilities of *Isopora* species to sedimentation or nutrients, the SRR rated them as “low-medium” importance to corals. Thus, we conclude that an unstudied *Isopora* species has some susceptibility to sedimentation and nutrients.

Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Isopora* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. Although there is no genus-level or species-specific information on the susceptibilities of *Isopora* species to collection and trade, there is no information suggesting they are not susceptible to these threats. Thus, we conclude that an unstudied *Isopora* species has some susceptibility to collection and trade.

In conclusion, an unstudied *Isopora* species is likely to be highly susceptible to ocean warming, and to have some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### *Isopora crateriformis*

##### Introduction

The SRR and SIR provided the following information on *I. crateriformis*’ morphology and taxonomy. Morphology was described as solid encrusting plates sometimes over one meter diameter, and taxonomy was described as having no taxonomic issues.

The public comments and information we gathered did not provide any new or supplemental information on morphology, but found that there is a moderate level of taxonomic uncertainty for *I. crateriformis*, and that there is a moderate level of species identification uncertainty for this species. Veron (2014) states that *I. crateriformis* is easily confused with *I. cuneata*, but Veron (2000; 2014), Wallace (1999b) and Wallace *et al.* (2012) continue to consider it a valid species, and it can be identified by experts (Fenner, 2014b). Thus, the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *I. crateriformis*’ distribution, habitat, and depth range. *Isopora crateriformis*’ distribution is from Sumatra (Indonesia) to American Samoa, and there are reports from the western and central Indian Ocean that need confirmation.

The SRR reported that this species is found most commonly in shallow, high-wave energy environments, from low tide to at least 12 meters deep, and has been reported from mesophotic depths (<50 m depth). The SIR reported that *I. crateriformis* is one of the most common species on upper reef slopes of southwest Tutuila, American Samoa. Rangewide, its predominant habitat is reef flats and lower reef crests, and it also occurs in adjacent habitats such as upper reef slopes.

Public comments did not provide any new or supplemental information on the distribution and habitat of *I. crateriformis*. *Isopora crateriformis* is reported from American Samoa (Kenyon *et al.*, 2010). Veron (2014) reports that *I. crateriformis* is confirmed in 13 of his 133 Indo-Pacific ecoregions, and is strongly predicted to be found in an additional 17. Wallace (1999b) reports its occurrence in three of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards *et al.* (2009) calculated the geographic range of this species at about 11 million km<sup>2</sup>, the 35th smallest range of the 114 species of *Acropora* and *Isopora* that she calculated. Worldwide, reef flats have a larger area than reef slopes (Vecsei, 2004). Most coral abundance surveys are carried out only on reef slopes, and thus may significantly underestimate the abundance of species such as *I. crateriformis* that are more common on reef flats than reef slopes.

#### Demographic Information

The SRR and SIR reported *I. crateriformis*' abundance as sometimes common and occasionally locally abundant. *Isopora crateriformis* has been reported as common in Indonesia (Veron, 2000) and as one of the most prevalent corals in American Samoa (Birkeland *et al.*, 1987).

Public comments did not provide information on the abundance of *I. crateriformis*. We gathered supplemental information, which includes the following. Richards *et al.* (2013b) conclude from their data that this species is globally widespread, locally restricted, and locally rare, and thus in the second rarest category with the predicted consequence of local extinction. Veron (2014) reports that *I. crateriformis* occupied 0.3 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.4 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare." Overall abundance was described as "occasionally common on reef flats."

Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *I. crateriformis*, the overall decline in abundance ("Percent Population Reduction") was estimated at 38 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences of species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *I. crateriformis* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *I. crateriformis*' life history. *Isopora crateriformis* is not prone to asexual reproduction via fragmentation, based on its semi-encrusting morphology. Supplemental information we gathered added that, while *I. crateriformis* often has a lower plate edge on colonies on slopes, colonies are very hard and thus unlikely to fragment often (D. Fenner, personal comm.). Public comments did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *I. crateriformis*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Isopora* of ocean warming, acidification, disease, sedimentation,

nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *I. crateriformis*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *I. crateriformis*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *I. crateriformis*' threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Isopora crateriformis* is not rated as moderately or highly susceptible to bleaching or disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Based on information for the genus *Isopora*, an unstudied species such as *I. crateriformis* can be predicted to have high susceptibility to ocean warming. Fenner (personal comm.) reports seeing a "white disease" or "tissue loss" on *I. crateriformis* that appeared similar to white syndrome during a brief disease outbreak in American Samoa, but prevalence was low. Since only one observation of disease on *I. crateriformis* is reported, it is likely that *I. crateriformis* has some susceptibility to disease. Based on species-specific and genus-level information described above, *I. crateriformis* likely is highly susceptible to ocean warming and likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *I. crateriformis* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *I. crateriformis*. We received criticism of that approach in public comments and in response we present a species-specific analysis of regulatory mechanisms in this final rule. Records confirm that *I. crateriformis* occurs in 13 Indo-Pacific ecoregions that encompass 17 countries' EEZs. The 17 countries are Australia, Brunei, Fiji, France (French Pacific Island Territories), Indonesia, Kiribati, Malaysia, New Zealand (Tokelau), Niue, Papua New Guinea,

Philippines, Samoa, Solomon Islands, Timor-Leste, Tonga, Tuvalu, and the United States (American Samoa). The regulatory mechanisms relevant to *I. crateriformis*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (41 percent with none limited in scope), coral collection (82 percent with 35 percent limited in scope), pollution control (53 percent with 12 percent limited in scope), fishing regulations on reefs (100 percent with 24 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *I. crateriformis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also common for the species, but 35 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are the least common regulatory mechanisms for the management of *I. crateriformis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the risk of extinction were the high susceptibility to threats inferred to be common to members of the family Acroporidae. It listed factors that reduce the risk of extinction including its prevalence in areas of heavy wave action as water motion can reduce bleaching vulnerability.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *I. crateriformis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic range extends from Sumatra (Indonesia) to American Samoa, and the Philippines to the GBR. On one hand, this moderates vulnerability to extinction because the central Pacific portion of its range is projected to have less than average warming over the foreseeable future, thus population in these areas will be less exposed to severe warming conditions. On the other hand, the species' geographic distribution exacerbates vulnerability to extinction because much of it lies within the western equatorial Pacific, an area projected to have the highest seawater temperatures in the foreseeable future. Its depth range is from zero to 12 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes at least reef flats, lower reef crests, and upper reef slopes. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Shallow areas may experience more frequent changing environmental conditions, extremes, high irradiance, and multiple simultaneous stressors, however, high energy environments experience high levels of mixing which can dilute adverse environmental conditions. Its absolute abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large

number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. However, its qualitative abundance is described as rare, which combined with its restricted depth distribution indicates it is likely that a high proportion of individuals will be affected by threats that are typically more severe in shallow habitats at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula, *I. crateriformis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we confirmed our listing determination for *I. crateriformis* as threatened. Based on the best available information provided above on *I. crateriformis*' spatial structure, demography, threat susceptibilities, and management, it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Isopora crateriformis* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), acidification (E), trophic effects of fishing (A), and nutrients (A, E), and predation (C). In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D);

(2) The majority of *Isopora crateriformis*' distribution is within the Coral Triangle and western equatorial Pacific, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Isopora crateriformis*' qualitative abundance is rare overall. Considering that much of the range of this species

includes areas where severe and increasing impacts are predicted, this level of abundance combined with its restricted depth distribution, leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from compensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these biological and environmental characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *I. crateriformis*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *I. crateriformis*' distribution is mostly in the Coral Triangle and western equatorial Pacific, which increases its extinction risk as described above, its habitat includes at least reef flats, lower reef crests, and upper reef slopes. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections.

(2) While *I. crateriformis*' depth range is primarily restricted to shallow habitats from zero to 12 meters, it has been reported from 50 meters in American Samoa. This moderates vulnerability to extinction over the foreseeable future because there may be depth refugia for *I. crateriformis* in some parts of its range from threats that are typically more severe in shallow habitats.

(3) Even though this species is considered rare, the absolute abundance of *I. crateriformis* is at least millions of colonies. In addition, it is "occasionally common on reef flats," a habitat type that has larger area than reef slopes. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high

proportion of its population from catastrophic events.

The combination of these biological and environmental characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *I. crateriformis*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Isopora cuneata*

##### Introduction

The SRR and SIR provided the following information on *I. cuneata*'s morphology and taxonomy. Morphology was described as sometimes flattened solid encrusting plates like *Isopora crateriformis*, but usually also forms "Mohawk" ridges parallel to the main wave motion or short flattened blades. Taxonomy was described as having no taxonomic issues.

Public comments and information we gathered provided the following information on the morphology or taxonomy of *I. cuneata*. *Isopora cuneata* has moderate taxonomic uncertainty, and moderate species identification uncertainty (Fenner, 2014b). Veron (2014) states that *I. cuneata* is easily confused with *I. palifera* which it closely resembles, but Veron (2000; 2014), Wallace (1999a) and Wallace *et al.* (2012) continue to consider it a valid species, and it can be identified by experts (Fenner, 2014b). Thus, we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *I. cuneata*'s distribution, habitat, and depth range. *Isopora cuneata*'s distribution is from the east coast of Africa to the central Pacific. One expert source does not recognize records from east Africa (Riegl, 1995), and the SRR questions whether they should be checked. The SRR reported that *I. cuneata*'s habitat is

shallow, high wave-energy environments. Its predominant habitat is high energy environments such as lower reef crests and reef flats, but it is also found in upper reef slopes, lagoons, and adjacent habitats. Its depth range is low tide to 15 meters deep.

Public comments provided the following information. One public comment stated that *I. cuneata* is widely distributed in Indonesian waters. We gathered supplemental information, including Veron (2014) which reports that *I. cuneata* is confirmed in 43 of his 133 Indo-Pacific ecoregions, and is strongly predicted to be found in an additional nine. Wallace (1999b) reports it from 11 of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards *et al.* (2009) calculated the geographic range of *I. cuneata* at 27 million km<sup>2</sup>, which was the 45th smallest among the 114 *Acropora* species for which ranges were calculated.

##### Demographic Information

The SRR and SIR reported *I. cuneata*'s abundance as generally common, occasionally locally abundant, and by far the most predominant of acroporids on some areas of the Great Barrier Reef.

Public comments provided the following information. One public comment stated that *I. cuneata* is very abundant in all Indonesian waters. We gathered supplemental information which included the following. Worldwide, reef flats have a larger area than reef slopes (Vecsei, 2004). Most coral abundance surveys are carried out only on reef slopes, and thus may significantly underestimate the abundance of species such as *I. cuneata* that are more common on reef flats and crests than reef slopes. Richards *et al.* (2013b) consider this to be a species that is globally widespread, locally restricted, and locally rare, and thus in the second rarest category with the predicted consequence of local extinction. Veron (2014) reports that *I. cuneata* occupied 5.1 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.76 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon." Overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this

species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *I. cuneata*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences of species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *I. cuneata* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *I. cuneata*’s life history. *Isopora cuneata* is a simultaneous hermaphroditic brooder. Larvae lack zooxanthellae, and in some areas the species can undergo several seasonal cycles of larval production. Its brooding life history allows *Isopora* species to locally dominate recruitment at Lord Howe Island, Australia; colonies of this genus also dominate the adult population there, suggesting brooding may drive community structure in remote areas. *Isopora cuneata* is not prone to asexual reproduction via fragmentation, based on its semi-encrusting morphology. The species shows moderate gene flow but little potential for large-scale dispersal. Public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *I. cuneata*’s threat susceptibilities, the SRR and SIR provided genus-level information for the

effects on *Isopora* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *I. cuneata*’s threats. *Isopora cuneata* showed intermediate bleaching susceptibility relative to other acroporids on the Great Barrier Reef in 2002, but showed severe losses in a 2006 mass bleaching event in the Marshall Islands, with only shaded bases of colonies surviving. *Isopora cuneata* was a common species in the *Acropora palifera* zone of the Chagos, but *I. cuneata* was nearly completely eliminated in 1998 and has not yet regenerated. Competition with algae significantly reduces growth rates of *I. cuneata*. At high latitude Lord Howe Island, *I. cuneata* was found to host five types of C zooxanthellae, with an ability to host specialized types in turbid environments. The species is also capable of photo-adapting to low light environments by increasing zooxanthellae density altering photosynthetic mechanisms (dark reaction enzymes or electron transport rates). The SRR and SIR did not provide any other species-specific information on the effects of these threats on *I. cuneata*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *I. cuneata* as follows: High vulnerability to ocean warming, moderate vulnerability to disease, acidification, trophic effects of fishing, and nutrients, and low vulnerability to sedimentation, sea-level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *I. cuneata*’s threats susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species’ threat susceptibilities. *Isopora cuneata* has been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Done *et al.* (2003b) reported that 20 percent of *I. cuneata* colonies on the GBR were affected by bleaching in 2002, and the species ranked 21st in proportion of coral colonies that were bleached or partially killed out of 52 studied *Acropora* and *Isopora* species. That is, 20 of the 52 species bleached more than *I. cuneata* and 31 bleached less.

*Isopora cuneata* has been rated as moderately or highly susceptible to disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Willis *et al.* (2004) report Black Band Disease on *I. cuneata* on No Name Reef in the Great Barrier Reef. No other

species-specific information is available for the susceptibility of *I. cuneata* to any other threat. Based on genus-level and species information, *I. cuneata* is predicted to likely be highly susceptible to ocean warming and to have some susceptibility to disease, acidification, trophic effects of fishing, nutrients, sedimentation, sea-level rise, predation, and collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *I. cuneata*. We received criticism of that approach in public comments and in response we present a species-specific analysis of regulatory mechanisms in this final rule. Records confirm that *I. cuneata* occurs in 43 Indo-Pacific ecoregions that encompass 23 countries’ EEZs. The 23 countries are Australia, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Japan, Madagascar, Mauritius, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Solomon Islands, Taiwan, Timor-Leste, Tonga, Tuvalu, United States (American Samoa, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *I. cuneata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (35 percent with four percent limited in scope), coral collection (65 percent with 30 percent limited in scope), pollution control (39 percent with 13 percent limited in scope), fishing regulations on reefs (100 percent with 13 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *I. cuneata* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat common for the species, but 30 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *I. cuneata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species’ vulnerability to extinction results from the combination of its spatial and

demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase potential extinction risk for *I. cuneata* are high susceptibility to threats inferred to be common to members of the family Acroporidae. A factor that reduces potential extinction risk is its prevalence in areas of heavy wave action, as water motion may reduce bleaching vulnerability.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *I. cuneata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to at least 15 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced

bleaching. Its habitat includes at least lower reef crests, reef flats, upper reef slopes, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. In addition, high energy environments experience high levels of mixing which can dilute adverse environmental conditions. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *I. cuneata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *I. cuneata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *I. cuneata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Isopora cuneata*'s distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range

are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitat it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future);

(2) *Isopora cuneata*' absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) It is a broadcast spawner and fast grower, enhancing recovery potential from mortality events as described in the Corals and Coral Reefs section above.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *I. cuneata* is not warranted for listing at this time under any of the listing factors.

## Genus *Montipora*

### Genus Introduction

The SRR and SIR provided an introduction to Indo-Pacific *Montipora*, covering geological history, taxonomy, life history, and threat susceptibilities of the genus as a whole. *Montipora* colonies are usually laminar, encrusting, massive, or branching, and usually have small protrusions between corallites, called papillae, tuberculae, or verrucae. The genus *Montipora* is the second largest genus of reef corals, with 75 species currently recognized, all in the Indo-Pacific.

### Genus Susceptibility to Threats

The SRR and SIR provided the following information on genus-level threat susceptibilities for *Montipora*. *Montipora* has a high susceptibility to bleaching, just below *Acropora* and *Millepora*. One species of *Montipora* has been tested for susceptibility to acidification, and was predicted to have 10 to 15 percent reductions in growth to pH by 2100. *Montipora* species have moderate susceptibility to diseases. *Montipora* has been characterized as a “sediment-intolerant” genus, but individual species range from tolerant to intolerant. Elevated nutrients have not been found to affect *Montipora* fecundity or fertilization. Crown-of-thorns seastar prey preferentially on *Montipora* and crown-of-thorns seastar outbreaks can cause substantial mortality. The genus *Montipora* is heavily used in the international aquarium trade.

The public comments did not provide any supplemental information on genus-level threat susceptibilities for Indo-Pacific *Montipora*. We gathered supplemental information, which provides the following genus-level information on threat susceptibilities of Indo-Pacific *Montipora* for ocean warming (thermal stress), coral disease, ocean acidification, and predation. With regard to thermal stress, almost all *Montipora* on the reef flats of two islands in the Thousand Islands of Indonesia died in the 1983 El Nino mass bleaching. A branching species, *Montipora digitata*, subsequently recovered on one island but not the other (Brown and Suharsono, 1990). In Moorea in 1998, *Montipora* was the third most affected genus by bleaching after *Montastraea* and *Acropora*, and second in mortality, with slightly less mortality than *Acropora* (Gleason, 1993). In Palau in 2000, many but not all *Montipora* species had heavy bleaching. In that event, 48 percent of all coral colonies of all species were bleached, with bleaching of different

genera and species ranging from none to very high, and mortality from none to near 100 percent (Bruno *et al.*, 2001). In Kenya in 1998, unprotected and protected sites were compared, and it was found that all *Montipora* species in unprotected sites died during the mass bleaching event while only half of the *Montipora* species in marine protected areas died (McClanahan *et al.*, 2001). In 1998 in Kenya, Tanzania, Mozambique, and Madagascar, 100 percent of *M. tuberculosa* colonies were affected by bleaching at the peak of bleaching, and 13 percent of the colonies died by the end of the bleaching event (Obura, 2001). In Raiatea, French Polynesia, in 2002, 53 percent of *Montipora tuberculosa* colonies and 18 percent *Montipora calculata* colonies were bleached respectively, the third and fifth most bleached species of the 11 coral species included in the study (Hughes *et al.*, 2003).

On the GBR in 2002, 18 species of *Montipora* ranged from zero to 77 percent affected by bleaching (Done *et al.*, 2003b). During mass bleaching in 1998, *Montipora* had a higher bleaching index in Kenya (64) than in Australia (38), but seawater temperatures were higher in Kenya (McClanahan *et al.*, 2004). At Mauritius in a bleaching event in 2004, *Montipora* had a bleaching index of 27, the 8th highest of the 32 genera recorded, which was 41 percent of the index of the genus with the highest index (McClanahan *et al.*, 2005a). In the western Indian Ocean in 1998–2005, *Montipora* had a bleaching index of 7.9 for eight countries, which was 34th highest of the 45 genera recorded, and 19 percent of the highest value (McClanahan *et al.*, 2007a). On Howland and Baker islands in the U.S. Pacific in early 2010, *Montipora* had a low percentage of bleaching with zero percent bleached on Baker and 4.8 percent on Howland. *Montipora* was the 13th most bleached genus out of 14 genera reported, with 4 percent as much bleaching as the most bleached genus (Vargas-Angel *et al.*, 2011). In a mass bleaching event in Western Australia, *Acropora* had the highest mortality, with *Montipora* having the second highest mortality (87 percent), while massive and encrusting corals (such as *Porites* and faviids) had much higher survival rates. Colonies less than 10 cm in size were not killed (Depczynski *et al.*, 2012).

In Okinawa, Japan, *Montipora* species experienced moderate drops in populations following the 1998 and 2010 mass bleaching episodes (Hongo and Yamano, 2013). At Laem Set at Samui Island in the western Gulf of Thailand in 1998, half of all colonies of

*M. tuberculosa* were partly bleached, and in 2010 all colonies were bleached. It was the 10th most bleached species out of 24 species in 1998, and was tied with seven other species out of 24 for most bleached in 2010. After the 1998 bleaching event, 75 percent of *M. tuberculosa* colonies had partial mortality, and after the 2010 event all colonies were dead. In 1998 it was tied for third place in mortality, and in 2010 it was in a three-way tie for most mortality (Sutthacheep *et al.*, 2013). In Kenya in 1998, 47 percent of *Montipora* colonies bleached, and of those, 73 percent died. Mortality was the fifth highest of any coral genus. The abundance of *Montipora* after 1998 in the western Indian Ocean decreased strongly in proportion to the number of degree heating weeks in 1998 (McClanahan *et al.*, 2007b). In Japan, one species of *Montipora* was a long-term winner following mass bleaching events (increasing from 0.2 percent to 2 percent cover), one species was a short term loser but a long term winner (decreasing from 1.8 percent to zero percent, and then increasing to 3.3 percent later), and one species was a long-term loser (decreasing from 1.6 percent to zero percent cover and staying there) (van Woesik *et al.*, 2011).

With regard to disease, a very low level of Black Band Disease was found on *Montipora* on the Great Barrier Reef, just 3 percent of the level on staghorn *Acropora* (Page and Willis, 2006). *Montipora* had a low susceptibility to Skeletal Eroding Band in the GBR, with a prevalence of 0.4 percent. Skeletal Eroding Band is the most prevalent disease on the GBR (Page and Willis, 2007). *Montipora* was had the second lowest rate of disease in American Samoa of the five genera with the most disease in American Samoa, with 0.08 percent prevalence. The highest rate of disease was *Acropora* with 0.39 percent prevalence. About 14 percent of sites in American Samoa have growth anomalies recorded on *Montipora*, compared to 71 percent for white syndrome on *Acropora*, so disease is relatively low on *Montipora* in American Samoa (Fenner and Heron, 2008). *Montipora* had the fourth highest prevalence of disease of coral genera in American Samoa at 0.06 percent, with the highest being *Acropora* at 0.85 percent (Aeby *et al.*, 2008). In Guam, *Montipora* had the fourth highest prevalence out of 12 genera, with 2 percent of colonies having disease compared to 6.7% for the highest genus (Myers and Raymundo, 2009). In New Caledonia, *Montipora* was tied for lowest disease prevalence among 12

genera, with less than 0.1 percent prevalence (Tribollet *et al.*, 2011). In Indonesia, *Montipora* had the eighth highest prevalence of disease out of 35 taxa, with 0.5 percent prevalence compared to 8 percent for the highest taxon (Haapkyla *et al.*, 2007).

With regards to predation, *Montipora* was the third most preferred prey of crown-of-thorns starfish out of the 10 most common genera on 15 reefs in the Great Barrier Reef, with a preference estimate 81 percent as high as the highest genus (*Acropora*) (De'ath and Moran, 1998). With regards to sedimentation, *M. aequituberculata* was the poorest species of 22 at clearing sediment off itself (Stafford-Smith, 1993).

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Montipora* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. Most studies report that the genus *Montipora* shows high rates of bleaching from ocean warming, almost as much as *Acropora* and *Millepora*. However, there was a range of bleaching responses reported for the genus *Montipora*, and a study of individual species showed a wide range of bleaching responses between species, with some not bleaching at all. While there is variability in the available information on the susceptibility of *Montipora* species to ocean warming, most of the information suggests high susceptibility. Thus, we conclude that an unstudied species of *Montipora* likely is highly susceptible to ocean warming. *Montipora* has been reported to have low to moderate rates of disease, thus we conclude that *Montipora* is likely to have some susceptibility to disease. One species of *Montipora* showed a reduction in growth at the acidification level anticipated for the end of the century, but gamete production was not affected. Thus we conclude that *Montipora* is likely to have some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or

SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Montipora* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. *Montipora* has been called a “sediment-intolerant” genus but there are variations in tolerance between species. We conclude that *Montipora* has some susceptibility to sedimentation. Elevated nutrients have had no effect on fecundity or fertilization success in *Montipora*, but competition with algae reduced settlement and survival of *Montipora* larvae. We conclude that *Montipora* has some susceptibility to nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Montipora* species is likely to have some susceptibility to sea-level rise. The little available information on predation of *Montipora* suggest that predators prefer to eat *Montipora* over most other genera. Thus, it is possible to predict that an unstudied *Montipora* species is likely to have some susceptibility to predation. The SRR rated ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall, and this threat was addressed at both the genus and species levels in the SRR. Because *Montipora* species are some of the more popular coral species to be collected and traded, an unstudied *Montipora* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Montipora* species is likely to have high susceptibility to ocean warming, and some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### *Montipora angulata*

##### Introduction

The SRR and SIR provided the following information on *M. angulata*'s morphology and taxonomy. Morphology was described as extensive encrusting

bases with short branches that form compact clumps and are pale brown in color. Genetic evidence places *M. angulata* in a clade with some other *Montipora* species, depending on which gene is used. The SRR treated *M. angulata* as a valid species.

The public comments and information we gathered did not provide information on morphology, and confirmed that the species has low uncertainty in morphological taxonomy. Clustering with other species in an initial genetics study gives moderate uncertainty. There is a moderate level of species identification uncertainty for this species, but Veron (2014) states that *M. angulata* is distinctive and Veron (2000; 2014), considers the species valid, and that it is sufficiently distinctive to be identified by experts (Fenner, 2014b). Thus, we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *M. angulata*'s distribution, habitat and depth. *Montipora angulata*'s distribution is from the northern and eastern Indian Ocean to the central Indo-Pacific to the central Pacific. Its habitat includes upper reef slopes, mid-slopes, lower reef crests, and reef flats, and its depth distribution is one to 20 m.

The public comments did not provide any new or supplemental information on *M. angulata*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 34 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 26.

##### Demographic Information

The SRR and SIR provided the following information on *M. angulata*'s abundance. *Montipora angulata*'s abundance is mostly rare.

The public comments did not provide any new or supplemental information on *M. angulata*'s abundance. We gathered supplemental information, which provided the following information. Worldwide, reef flats have a larger area than reef slopes (Vecsei, 2004), and most coral abundance surveys are carried out only on reef slopes, and thus may significantly underestimate the abundance of species such as *M. angulata* that occur primarily on reef flats. Veron (2014) reports that *M. angulata* occupied 0.34 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had

a mean abundance rating of 1.3 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare," and overall abundance was also described as "rare." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (Carpenter *et al.*, 2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *M. angulata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 39 percent, and the decline in abundance before the 1998 bleaching event ("Broadcast Percent Population Reduction") was estimated at 16 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *M. angulata* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *M. angulata*'s life history. The sexuality and reproductive modes have been determined for 35 other species of *Montipora*, all of which are hermaphroditic broadcast spawners. Also, the larvae of all other *Montipora* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. Thus, these characteristics likely occur in *M. angulata* as well. The public comments

and information we gathered provided no additional biological information.

#### Susceptibility to Threats

To describe *M. angulata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Montipora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR also provided the following species-specific information on *M. angulata*'s threats. *Montipora angulata* contains Clade C zooxanthella; this clade varies in its thermal tolerance, but is generally less resistant to bleaching than Clade D. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *M. angulata*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *M. angulata*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, nutrients, and predation, and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *M. angulata*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Montipora angulata* has been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). In one study, colonies of *M. angulata* contained Clade C zooxanthellae (Good *et al.*, 2005). However, other *Montipora* species are known to contain Clade D zooxanthellae, depending on colony location or depth (LaJeunesse *et al.*, 2004b; Stat *et al.*, 2009). Thus, it is possible that broader sampling of *M. angulata* colonies would show that this species also hosts Clade D zooxanthellae in some habitats. There are no studies of the effects of any other threats on *M. angulata*. Based on species-specific and genus-level information described above, *M. angulata* is likely to be highly susceptible to ocean warming and likely to have some susceptibility to disease, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *M. angulata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory

mechanisms or conservation efforts for *M. angulata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *M. angulata* occurs in 34 Indo-Pacific ecoregions that encompass 17 countries' EEZs. The 17 countries are Australia (including Cocos-Keeling Islands), Brunei, Cambodia, China, India (Andaman and Nicobar Islands), Indonesia, Japan, Malaysia, Myanmar, Papua New Guinea, Philippines, Solomon Islands, Sri Lanka, Taiwan, Thailand, Timor-Leste, and Vietnam. The regulatory mechanisms relevant to *M. angulata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (29 percent with 6 percent limited in scope), coral collection (41 percent with 18 percent limited in scope), pollution control (35 percent with 12 percent limited in scope), fishing regulations on reefs (100 percent with 18 percent limited in scope), and managing areas for protection and conservation (94 percent with none limited in scope). The most common regulatory mechanisms in place for *M. angulata* are reef fishing regulations and area management for protection and conservation. General coral protection, pollution control, and coral collection laws are much less common regulatory mechanisms for the management of *M. angulata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for this species include its rare abundance combined with presumed generic vulnerability to a range of threats including disease, bleaching, and predation as well as potentially increasing threats from collection and trade. It listed factors that reduce potential extinction risk including its relatively wide geographic distribution.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our

assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. angulata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many coral reef ecoregions in the central Indo-Pacific oceans. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from one to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower temperatures than surface waters due to local and micro-habitat variability in environmental conditions, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes, mid-slopes, lower reef crests, and reef flats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Although its qualitative abundance is described as rare, its absolute abundance is at least millions of colonies, which combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach,

*M. angulata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. angulata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including a more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *M. angulata*'s spatial structure, demography, threat susceptibilities, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Montipora angulata*'s distribution across the central Indo-Pacific is spread over a large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future) and

(2) While *M. angulata*'s qualitative abundance is characterized as rare, the species consists of at least millions of colonies that are broadly distributed, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *M. angulata* is not warranted for listing at this time under any of the listing factors.

#### *Montipora australiensis*

##### Introduction

The SRR and SIR provided the following information on *M. australiensis*' morphology and taxonomy. Morphology was described as thick plates and irregular columns that are pale brown, and the taxonomy was described as having no taxonomic issues.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *M. australiensis*. There is a moderate level of species identification uncertainty for this species, and Veron (2014) states that *M. australiensis* is easily confused with several other *Montipora*, but Veron (2000; 2014) also considers the species valid, and we consider it is sufficiently distinctive to be identified by experts (Fenner, 2014b). Thus, we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *M. australiensis*' distribution, habitat, and depth range. *Montipora australiensis*' distribution is broad longitudinally, including eastern Africa, the central

Indo-Pacific, and the entire central Pacific, its habitat is shallow reef environments with high wave action, and its depth range is given as 2 to 30 meters, which the SRR noted seems at odds with the shallow reef environment habitat description.

The public comments did not provide any new or supplemental information on *M. australiensis*' distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 17 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 16. Veron 2014 also provides a more recent geographic range description and map for this species which includes areas in the western Indian Ocean, and most ecoregions between southern Japan and the GBR, and between western Australia and Vanuatu. We did not gather or receive any information on habitat or depth, thus we interpret the available information as follows: Its predominant habitat is upper reef slopes, lower reef crests, and reef flats, and it likely also occurs on mid-slopes and possibly other habitats at depths of two to 30 m.

#### Demographic Information

The SRR and SIR provided the following information on *M. australiensis*' abundance. *Montipora australiensis* has been reported as rare.

The public comments did not provide any new or supplemental information on *M. australiensis*' abundance. We gathered supplemental information, including Veron (Veron, 2014), which reports that *M. australiensis* occupied 0.40 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.50 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare." Overall abundance was described as "usually rare." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *M. australiensis*, the overall decline in abundance ("Percent Population Reduction") was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14. However, as summarized above in the

Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *M. australiensis* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *M. australiensis*' life history. Sexuality and reproductive modes have been determined for 35 other species of *Montipora*, all of which are hermaphroditic broadcast spawners. Although specific observations have not been published for this species, the larvae of all other *Montipora* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. It is likely these characteristics occur in this species as well. The public comments and information we gathered provided no additional biological information.

#### Susceptibility to Threats

To describe *M. australiensis*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Montipora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any species-specific information on the effects of these threats on *M. australiensis*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *M. australiensis*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, acidification, trophic effects of reef fishing, nutrients, and predation, and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *M. australiensis*' threats susceptibilities. We gathered the following species-specific and genus-level information on this species' threat susceptibilities. *Montipora australiensis* has been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). There are no species-specific studies of the effects of any threats on *M. australiensis*. Based on the genus-level information described above, *M. australiensis* likely is highly susceptible to ocean warming, and likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *M. australiensis* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *M. australiensis*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *M. australiensis* occurs in 17 Indo-Pacific ecoregions that encompass 13 countries' EEZs. The 13 countries are Australia, Cambodia, France (French Pacific Island Territories), Indonesia, Japan, Madagascar, Mauritius, Papua New Guinea, Philippines, Seychelles, Solomon Islands, Thailand, and Vietnam. The regulatory mechanisms relevant to *M. australiensis*, first described as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (31 percent with 8 percent limited in scope), coral collection (46 percent with 8 percent limited in scope), pollution control (38 percent with 23 percent limited in scope), fishing regulations on reefs (100 percent with 8 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *M. australiensis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 23 percent of pollution control laws are limited in scope and may not provide

substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *M. australiensis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated the factors that increase the potential extinction risk for *M. australiensis* include its rare abundance combined with presumed generic vulnerability to a range of threats including disease, bleaching, and predation. It listed factors that reduce potential extinction risk including its relatively wide geographic distribution.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. australiensis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is mostly limited to parts of the Coral Triangle and the western Indian Ocean. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range of two to at least 30 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the

species occurs. Its habitat includes upper reef slopes, lower reef crests, reef flats, and mid-slopes. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Additionally, habitats in high wave action have increased water mixing that can reduce irradiance and dilute other adverse environmental conditions. Its absolute abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. However, its qualitative abundance is described as rare, which combined with its restricted depth distribution indicates it is likely that a high proportion of individuals will be affected by threats that are typically more severe in shallow habitats at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula, *M. australiensis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we confirmed the listing determination for *M. australiensis* as threatened. Based on the best available information provided above on *A. lokani*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Montipora australiensis* is highly susceptible to ocean warming (ESA Factor E), and susceptible to disease (C), ocean acidification (E), trophic effects of fishing (A), and predation (C), and nutrients (A, E). These threats are expected to continue and worsen into the future. In addition, existing regulatory mechanisms for global threats

that contribute to extinction risk for the species are inadequate (D);

(2) The majority of *Montipora australiensis*' distribution is within the Coral Triangle which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Montipora australiensis*' qualitative abundance is rare. Considering the limited range of this species in an area where severe and increasing impacts are predicted, this level of abundance leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *M. australiensis*' spatial structure, demography, threat susceptibilities, and management also indicate that the species the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *M. australiensis*' range is mostly constrained to the Coral Triangle which increases its extinction risk as described above, other areas within its range are projected to have less than average warming and acidification, such as the western Indian Ocean. Additionally, its habitat includes upper reef slopes, lower reef crests, and reef flats, and it likely also occurs on mid-slopes. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral

Habitat and Threats Evaluation sections; and

(2) While *M. australiensis*' qualitative abundance is characterized as rare, its absolute abundance is at least millions of colonies. There is no evidence that this species is of such low abundance that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *M. australiensis*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (*i.e.*, GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Montipora calcarea*

##### Introduction

The SRR and SIR provided the following information on *M. calcarea*'s morphology and taxonomy. The morphology was described as irregular thick plates with columnar upgrowths and are pale brown or blue in color, and taxonomy was described as having no taxonomic issues.

The public comments and information we gathered did not provide information on morphology, and confirmed that there are no known taxonomic problems for *M. calcarea*. There is a moderate level of species identification uncertainty for this species, and Veron (2014) states that *M. calcarea* is easily confused with several other *Montipora*, but Veron (2000; 2014), considers the species valid, and we consider it is sufficiently distinctive to be identified by experts (Fenner, 2014b). Thus, we conclude the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *M. calcarea*'s distribution, habitat, and depth range. *Montipora calcarea*'s range is fairly

wide but somewhat discontinuous, it is known from the Red Sea and east Africa, parts of the Coral Triangle, northwestern Australia, and the central Pacific. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, and reef flats, and its depth range as 0 to 20 m.

The public comments did not provide any new or supplemental information on *M. calcarea*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 25 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 24. The public comments and information we gathered provided nothing additional on *M. calcarea*'s habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *M. calcarea*'s abundance. The abundance of *M. calcarea* has been reported as rare, but may be locally abundant in some areas.

The public comments did not provide any new or supplemental information on *M. calcarea*'s abundance, but the supplemental information provided the following. Surveys in Indonesia recorded the species at eight of 51 sites (Donnelly *et al.*, 2003), and nine of 39 sites (Turak and DeVantier, 2003). Veron (2014) reports that *M. calcarea* occupied 5.8 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.35 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare." Overall abundance was described as "usually rare." As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (Carpenter *et al.*, 2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *M. calcarea*, the overall decline in abundance ("Percent Population Reduction") was estimated at 34 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 13 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be

interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *M. calcarea* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *M. calcarea*'s life history. The reproductive characteristics of *M. calcarea* have not been determined. However, sexuality and reproductive modes have been determined for 35 other species of *Montipora*, all of which are hermaphroditic broadcast spawners. Although specific observations have not been published for this species, the larvae of all other *Montipora* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. It is likely these characteristics occur in this species as well. The public comments and information we gathered provided no additional biological information.

##### Susceptibility to Threats

To describe *M. calcarea*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Montipora* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *M. calcarea*'s threats. *Montipora calcarea* was not susceptible to algal or sediment impacts in anthropogenically impacted waters in Egypt, but one of the studies appears to be a study of the effects of low tide. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *M. calcarea*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *M. calcarea*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, nutrients and predation, and

low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *M. calcarea's* threats, but we gathered the following species-specific and genus-level information on this species' threat susceptibilities. *Montipora calcarea* has been rated as moderately or highly susceptible to bleaching but not disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). There are no species-specific studies of the effects of any threats on *M. calcarea*. Based on the genus-level and species information described above, *M. calcarea* likely is highly susceptible to ocean warming, and also likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *M. calcarea* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *M. calcarea*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *M. calcarea* occurs in 25 Indo-Pacific ecoregions that encompass 28 countries' EEZs. The 28 countries are Australia, Brunei, Djibouti, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Madagascar, Malaysia, Mauritius, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Thailand, Timor-Leste, Tonga, Tuvalu, United States (American Samoa), Vietnam, and Yemen. The regulatory mechanisms relevant to *M. calcarea*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (29 percent with 4 percent limited in scope), coral collection (61 percent with 25 percent limited in scope), pollution control (43 percent with 11 percent limited in scope), fishing regulations on reefs (100 percent with 14 percent limited in scope), and managing areas for protection and conservation (93 percent with none limited in scope). The most common regulatory mechanisms in place for the species are

reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for *M. calcarea*, but 25 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *M. calcarea*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *M. calcarea* include its rare abundance combined with presumed generic vulnerability to a range of threats including disease, bleaching, and predation. It listed factors that reduce potential extinction risk including its relatively wide geographic distribution.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. calcarea*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes the Red Sea and many of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its

depth range is from zero to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, and reef flats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Although its qualitative abundance is described as rare, its absolute abundance is at least tens of millions of colonies, which combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *M. calcarea* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. calcarea* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *M. calcarea's* spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to

become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Montipora calcarea*'s distribution across the Red Sea, Indian Ocean and the central Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) While *M. calcarea*'s qualitative abundance is characterized as rare, the species consists of at least tens of millions of colonies that are broadly distributed, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *M. calcarea* is not warranted for listing at this time under any of the listing factors.

### *Montipora caliculata*

#### Introduction

The SRR and SIR provided the following information on *M. caliculata*'s morphology and taxonomy. Morphology was described as brown or blue and massive, and corallites are a mixture of immersed and foveolate (in a funnel shape). The taxonomy was described as having no taxonomic issues.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there is little taxonomic uncertainty for *M. caliculata*. There is a moderate level of species identification uncertainty for this species, and Veron (2014) states that *M. caliculata* is easily confused with several other *Montipora*, but Veron (2000; 2014) also considers the species valid, and we consider it is sufficiently distinctive to be identified by experts (Fenner, 2014b). Thus, the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *M. caliculata*'s distribution, habitat, and depth range. *Montipora caliculata* is found in the central Indo-Pacific and the Pacific as far east as the Pitcairn Islands. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, and reef flats, and its depth range extends as deep as 20 m.

The public comments did not provide any new or supplemental information on *M. caliculata*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 53 of his 133 Indo-Pacific ecoregions, and strongly predicted to occur in an additional 29. The public comments and information we gathered provided nothing additional on *M. caliculata*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *M. caliculata*'s abundance. *Montipora caliculata* has been reported as uncommon.

The public comments did not provide any new or supplemental information on *M. caliculata*'s abundance. We gathered supplemental information, including surveys in Indonesia and Vietnam that recorded the species at ten of 51 sites (Donnelly *et al.*, 2003), and five of seven sites (Latypov, 2011), respectively. Veron (2014) reports that *M. caliculata* occupied 12.1 percent of 2,984 dive sites sampled in 30

ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.55 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common." Overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (Carpenter *et al.*, 2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *M. caliculata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *M. caliculata* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *M. caliculata*'s life history. The sexuality and reproductive modes have been determined for 35 other species of *Montipora*, all of which are hermaphroditic broadcast spawners. Although specific observations have not been published for this species, the larvae of all other *Montipora* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their

photosynthesis. It is likely these characteristics occur in this species as well. The public comments and information we gathered provided no additional biological information.

#### Susceptibility to Threats

To describe *M. caliculata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Montipora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR also provided the following species-specific information on *M. caliculata*'s threats. *Montipora caliculata* is known to contain mycosporine-like amino acids, which can play a role in reducing bleaching exposure. However, *M. caliculata* was the 7th most susceptible to bleaching of the 18 *Montipora* listed on the Great Barrier Reef, but showed only moderate bleaching (~ 20%, or less than half as susceptible as congener *Montipora tuberculosis*) in French Polynesia during the 2002 bleaching event. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *M. caliculata*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *M. caliculata*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, nutrients and predation, and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *M. caliculata*'s threats, but we gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Montipora caliculata* has been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Done *et al.* (2003b) report 50 percent of colonies of *M. caliculata* were affected by bleaching on the GBR in 2002. This was more than 11 out of 17 *Montipora* species and 67 percent as much as the species that bleached the most. No other species-specific information is available for the susceptibility of *M. caliculata* to any other threat. Based on genus-level and species information described above, *M. caliculata* may be highly susceptible to ocean warming, and likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, predation, and collection and trade. The available information does not support more

precise ratings of the susceptibilities of *M. caliculata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *M. caliculata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *M. caliculata* occurs in 53 Indo-Pacific ecoregions that encompass 36 countries' EEZs. The 36 countries are Australia, Brunei, Cambodia, China, Djibouti, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Japan, Kiribati, Madagascar, Malaysia, Marshall Islands, Myanmar, Nauru, New Zealand (Cook Islands, Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Taiwan, Thailand, Timor-Leste, Tonga, Tuvalu, United Kingdom (Pitcairn Islands), United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms relevant to *M. caliculata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (28 percent with three percent limited in scope), coral collection (58 percent with 31 percent limited in scope), pollution control (36 percent with eight percent limited in scope), fishing regulations on reefs (97 percent with 19 percent limited in scope), and managing areas for protection and conservation (92 percent with six percent limited in scope). The most common regulatory mechanisms in place for *M. caliculata* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat common for the species, but 31 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *M. caliculata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future

projections of threats. The SRR stated that factors that increase the potential extinction risk for *M. caliculata* include its presumed generic vulnerability to a range of threats including disease, bleaching, and predation. It listed factors that reduce potential extinction risk including its relatively wide geographic distribution.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. caliculata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is down to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, and reef flats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with

spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *M. caliculata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. caliculata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *M. caliculata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Montipora caliculata*'s distribution from the Red Sea across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution throughout the entire region and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to

occur uniformly throughout the species range within the foreseeable future; and

(2) *Montipora caliculata*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *M. caliculata* is not warranted for listing at this time under any of the listing factors.

#### *Montipora dilatata/flabellata/turgescens* Introduction

As discussed above in the response to comments, public comments did not provide any new or supplemental information, nor did we find any new or supplemental information, contradicting the key study used by the SRR to lump these nominal species (see SRR for further explanation) into one species as a listable entity under the ESA. The SRR and SIR provided the following information on *M. dilatata/flabellata/turgescens*' morphology and taxonomy. *Montipora dilatata* morphology was described as colonies that are encrusting to submassive, with irregular branch-like upgrowths, and are pale to dark brown in color. *Montipora flabellata* morphology was described as colonies that are encrusting, with irregular lobes, and usually blue in color, but

sometimes brown or purple. *Montipora turgescens* morphology was described as colonies that are massive, flat, hemispherical or columnar and are brown, cream, or purple in color.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that *M. dilatata/flabellata/turgescens* has little taxonomic uncertainty, but a moderate level of species identification uncertainty. One public comment stated that *M. dilatata* and *M. flabellata* were described by Studer, 1901, instead of Dana, 1846 as stated in the SRR. Veron (2014) states that *M. dilatata* and *M. flabellata* are apparently distinctive, and *M. turgescens* is distinctive and Veron (2000; 2014) considers these species valid, so we consider these morphological variations of this single species sufficiently distinctive to be identified by experts (Fenner, 2014b). Thus, we consider the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *M. dilatata/flabellata/turgescens*' distribution, habitat, and depth range. The distribution of this species is the sum of the distributions of the three nominal species. *Montipora dilatata* and *M. flabellata* are in Hawaii and *M. turgescens* ranges from the Red Sea and east Africa to French Polynesia, thus the whole entity ranges from the Red Sea and east Africa to Hawaii and French Polynesia. This species' habitat includes at least upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, reef flats, and lagoons, and extends to 30 m deep.

The public comments provided the following supplemental information. One public comment stated that *M. turgescens* that was reported by Fenner (2005) to be restricted within Hawaii and the Northwestern Hawaiian Islands. We gathered supplemental information which provided the following. *Montipora dilatata* was previously only known from Hawaii, but has recently been reported to occur in the northern and southern Line Islands of Kiribati and the Cook Islands (Veron, 2014). Within Hawaii, *M. dilatata* has only been observed at Kaneohe Bay on Oahu and at Laysan Island in the northwestern Hawaiian Islands. However, the Laysan location has not been confirmed recently and may need further investigation. *Montipora flabellata* was also previously known

only from Hawaii (Veron, 2000), but has recently been reported to occur in the northern Line Islands of Kiribati (Veron, 2014). In contrast, *M. turgescens* is broadly distributed throughout the Indo-Pacific from South Africa and Socotra Island to Hawaii and French Polynesia, and from Japan to the mid-latitudes in Australia (Veron, 2014). Veron (Veron, 2014) confirms *M. dilatata* in four of his 133 Indo-Pacific ecoregions (northwestern and main Hawaiian Islands and the northern and southern Line Islands), *M. flabellata* from three of the same four ecoregions (all but the southern Line Islands), and *M. turgescens* in 71 (including both Hawaii ecoregions but neither Line Islands ecoregions). Thus, *M. dilatata/flabellata/turgescens* is confirmed in 73 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 30 (Veron, 2014).

*Montipora dilatata* is reported from subtidal environments (Veron, 2000). In the only location within the main Hawaiian Islands where *M. dilatata* is known, Kaneohe Bay on Oahu, it is limited to shallow water protected from wave action. *Montipora flabellata* is reported from shallow reef environments, and *M. turgescens* is reported from most reef environments (Veron, 2000). *Montipora dilatata* and *M. flabellata* are both reported from 1 to 10 m depth, whereas *M. turgescens* has been reported to 30 m depth (Carpenter *et al.*, 2008). Thus we consider the depth range for this species to be from one to at least 30 meters.

#### Demographic Information

The SRR and SIR provided the following information on *M. dilatata/flabellata/turgescens*' abundance. *Montipora dilatata* is rare, *M. flabellata* is the 5th most common coral in Hawaii, and *M. turgescens* is described as common.

Public comments provided the following. One comment provided quantitative transect data from Hawaii that included coral cover measures of *M. flabellata*. At Kahului Harbor channel entrance, *M. flabellata* was the most abundant coral. At several other sites, *M. flabellata* was not recorded or was recorded at low levels. Supplemental information provided the following. Veron (2014) reports that *M. dilatata* and *M. turgescens* occupied 0.03 and 16.66 percent respectively of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 3.0 and 1.40 respectively on a 1 to 5 rating scale at those sites in which it was found. The "mean abundance when present" rating of 3.0 for *M. dilatata* was the highest of all species in

Veron (2014), indicating that it was highly abundant at the few sites where it was observed. Based on this semi-quantitative system, *M. dilatata* and *M. turgescens*' abundances were characterized as "rare" and "common" respectively, and overall abundances were also described as "rare" and "common" respectively. *Montipora flabellata* was not encountered in their surveys because they did not survey in Hawaii (Veron, 2014). Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

*Montipora dilatata* and *M. turgescens* are rare in the main Hawaiian Islands, thus they are not recorded in the Hawaii Coral Reef Assessment and Monitoring Program (CRAMP) data-sets. In contrast, CRAMP results indicate that *M. flabellata* has an overall statewide mean cover of 2.2 percent, making it the fifth most abundant coral in the main Hawaiian Islands (CRAMP, 2008a). Jokiel and Brown (2004) reported *M. flabellata* as the sixth most abundant coral in the main Hawaiian Islands, with 0.7 percent cover. A model predicted that *M. flabellata* was sixth in coral cover of all corals in the Main Hawaiian Islands, with about 0.3 percent cover (Franklin *et al.*, 2013). Kenyon and Brainard (2006) reported that *M. flabellata* and *M. turgescens* along with *M. capitata* dominate many backreef locations on the northern three atolls in the Northwestern Hawaiian Islands. Hunter (2011) reported that the number of *M. dilatata* colonies in Kaneohe Bay, Oahu has increased with increasing search effort, and in 2010 a total of 43 confirmed *M. dilatata* colonies were located. This is the only location in the main Hawaiian Islands where *M. dilatata* is known to occur.

There is no overall abundance trend information for *M. dilatata*, *M. flabellata*, or *M. turgescens*, but *M. flabellata* has been monitored on some time-series transects in Hawaii. Dollar and Grigg (2004) monitored coral cover over 12 and 20 year periods at three sites in Hawaii, each with multiple transects: a semi-enclosed embayment on Maui and two open coastal sites on Kauai and the Big Island. At the Maui site, overall live coral cover declined by approximately 33 percent from 1990 to 2002. *Montipora flabellata* cover increased from 6.9 to 7.1 percent of total live coral cover, and was the fifth most abundant coral. At the Kauai site, overall live coral cover increased by approximately 30 percent from 1983 to

2002. *Montipora flabellata* increased from 7.4 to 14.3 percent of total live coral cover and was the fourth most abundant coral. At the Big Island site, overall live coral cover increased by approximately 50 percent from 1983 to 2002, but *M. flabellata* was not present during the study (Dollar and Grigg, 2004).

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *M. turgescens*, the overall decline in abundance ("Percent Population Reduction") was estimated at 20 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 9 percent. Estimates for *M. dilatata* and *M. flabellata* were not available. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years. These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *M. turgescens* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited information.

#### Other Biological Information

The SRR and SIR provided the following information on *M. dilatata/flabellata/turgescens*' life history. *Montipora dilatata/flabellata/turgescens* is a hermaphroditic broadcast spawner. The public comments and information we gathered provided no additional biological information.

#### Susceptibility to Threats

To describe *M. dilatata/flabellata/turgescens*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Montipora* of ocean warming, disease, ocean acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *M. dilatata/flabellata/turgescens*' threats. *Montipora dilatata* and *M. flabellata* are highly susceptible to

bleaching, with substantial local declines of *M. dilatata* in Kāneʻohe Bay, Hawaiʻi, from bleaching mortality. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *M. dilatata/flabellata/turgescens*. We interpreted the susceptibility and exposure information from the SRR and SIR in the proposed rule for *M. dilatata/flabellata/turgescens*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, nutrients, and predation, and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *M. dilatata/flabellata/turgescens*' threats, but we gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Montipora dilatata*, *M. flabellata*, and *M. turgescens* have each been rated as moderately or highly susceptible to bleaching but not to disease, however, these ratings are not based on species-specific data (Carpenter *et al.* 2008). With regard to thermal stress, in the Northwest Hawaiian Islands, *M. turgescens* bleached much less severely than *Montipora capitata* in 2002 (G. Aeby personal comm.). Kenyon and Brainard (2006) report that in 2004, *M. capitata* and *M. turgescens* had high levels of bleaching in the northern three atolls, with up to 100 percent bleaching in some areas. *Montipora flabellata*, though, had very low levels of bleaching (1.2 to 4.7 percent). Jokiel and Brown (2004) reported that *M. dilatata* and *M. flabellata* had low resistance to bleaching in 1996 in Hawaii. *Montipora dilatata* was the most sensitive species to bleaching in Kaneohe Bay in 1996. It was the first to bleach and few survived the event (Jokiel and Brown, 2004). The majority of the species-specific and genus-level information above suggests that *M. dilatata/flabellata/turgescens* likely is highly susceptible to warming-induced bleaching.

With regard to disease, *M. turgescens* is specifically described with mortality from a rapid tissue-loss ("white") syndrome in the Northwestern Hawaiian Islands, and this condition affected more than 21 percent of *Montipora* colonies in a 2003 survey (Aeby, 2006). In the main Hawaiian Islands, an outbreak of filamentous bacterial diseases began in 2012 on Kauai, and continued in 2013, heavily affecting the *Montipora* species on these reefs, including *Montipora capitata*, *M. flabellata*, and *M. patula* (Work, 2013). This species appears to be highly

susceptible to these diseases when environmental conditions are degraded, especially the larger colonies (Thierry Work, personal comm.).

Based on genus-level and species information described above, *M. dilatata/flabellata/turgescens* likely is highly susceptible to ocean warming, and likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, predation, and collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *M. dilatata/flabellata/turgescens*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *M. dilatata/flabellata/turgescens* occurs in 73 Indo-Pacific ecoregions that encompass 30 countries' EEZs. The 30 countries are Australia (including Norfolk Island), Brunei, Cambodia, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (including Andaman and Nicobar Islands), Indonesia, Japan, Kiribati, Madagascar, Malaysia, Mauritius, Myanmar, New Zealand (Cook Islands), Palau, Papua New Guinea, Philippines, Seychelles, Solomon Islands, South Africa, Sri Lanka, Taiwan, Thailand, Timor-Leste, United States (Hawaii, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms relevant to *M. dilatata/flabellata/turgescens*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (33 percent with 10 percent limited in scope), coral collection (53 percent with 23 percent limited in scope), pollution control (43 percent with 10 percent limited in scope), fishing regulations on reefs (97 percent with 20 percent limited in scope), and managing areas for protection and conservation (97 percent with none limited in scope). The most common regulatory mechanisms in place for to *M. dilatata/flabellata/turgescens* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 23 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are less

common regulatory mechanisms for the management of *M. dilatata/flabellata/turgescens*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *M. dilatata/flabellata/turgescens* include its presumed generic vulnerability to a range of threats including ocean warming, disease, predation, as well as documented declines in Hawaiʻi of the *M. dilatata* component. Factors that reduce potential extinction risk are the common occurrence and relatively wide geographic distribution of the *M. turgescens* component.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. dilatata/flabellata/turgescens*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat sub-section, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes nearly all of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to at least 30 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than

surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, reef flats, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of tens to hundreds of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *M. dilatata/flabellata/turgescens* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. dilatata/flabellata/turgescens* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *M. dilatata/flabellata/turgescens*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Montipora dilatata/flabellata/turgescens*' distribution across the Indian Ocean and most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Montipora dilatata/flabellata/turgescens*' absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *M. dilatata/flabellata/turgescens* is not warranted for listing at this time under any of the listing factors.

#### *Montipora lobulata*

##### Introduction

The SRR and SIR provided the following information on *M. lobulata*'s morphology and taxonomy. Colonies of *Montipora lobulata* are mottled brown or white and submassive. Colony surfaces consist of irregular mounds. There are no taxonomic issues for *M. lobulata*.

The public comments did not provide any new or supplemental information on *M. lobulata*'s morphology and taxonomy. We gathered supplemental information on this species, which indicates a very high level of species identification uncertainty for this species. *Montipora lobulata* is too difficult to identify on reefs, even for experts, for the data collected on it to be reliable. Veron (2014) states that *M. lobulata* has a poorly known distribution and his distribution map is not suitable for analysis. Although Veron (2000; 2014), considers the species valid, we conclude it not sufficiently distinctive to be reliably identified (Fenner, 2014b). Thus, we do not consider the *M. lobulata* distribution and abundance information in the SRR or SIR to be sufficiently reliable and are unable to provide a reliable species description for *M. lobulata* in this final rule.

##### Listing Determination

In the proposed rule using the determination tool formula approach, *M. lobulata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

Based on the lack of information on *M. lobulata*'s distribution, abundance, and threat susceptibilities due to this species' identification uncertainty, we believe there is not sufficient evidence to support a listing determination of threatened or endangered. Therefore, we find that listing is not warranted at this time under any factor.

#### *Montipora patula/veirilli*

##### Introduction

The SRR and SIR provided the following information on *M. patula/veirilli*'s morphology and taxonomy. Morphology was described as encrusting or tiered plates that are tan in color, most often with purple polyps.

Due to taxonomic issues from recent genetic and micro-morphological analyses, the BRT chose to evaluate extinction risk of *Montipora patula/verrilli* as a species since they are indistinguishable genetically and micro-morphologically.

The public comments provided the following information on morphology and taxonomy. One public comment stated that there are subtle but consistent differences between the two nominal species, and despite genetic analysis showing strong similarity between the two species, it cannot be conclusive until more of the genome is analyzed. A second public comment stated that since the combining of morphological species into a single entity was only done for two groups of species in Hawaii and for none of the other species around the world, for consistency these species should be considered separately. The commenter stated that these groupings are based on a single scientific publication that suggests, but does not state conclusively, that these species contain the same identical genomes and that combining them makes it so that differences between them in abundance and physiological characteristics cannot be separated. The group as a whole, suggested the commenter, might have one status while species within the group could have another. As discussed above in the response to comments, public comments did not provide any new or supplemental information contradicting the SRR to lump these nominal species (see SRR for further explanation) into one species as a listable entity under the ESA.

Supplemental information we gathered confirms the known taxonomic problems for *M. patula/verrilli*, and reports that there is a moderate level of species identification uncertainty for this species. *Montipora patula* and *M. verrilli* are similar (Veron, 2000; Veron, 2014; Wallace, 1999b), and may be indistinguishable (Fenner, 2005). However, the species *M. patula/verrilli* is distinctive and not difficult to identify by experts (Fenner, 2014b). Veron (2014) states that *M. patula* is very similar to *M. verrilli* and Veron (2000; 2014) considers the species valid. As already stated, we consider *M. patula/verrilli* is sufficiently distinctive to be identified by experts (Fenner, 2014b). Thus, we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *M. patula/*

*verrilli*'s distribution, habitat, and depth range. *Montipora patula/verrilli* has a very restricted range, centered on the Main and Northwestern Hawaiian Islands. *Montipora verrilli* has been reported from some other locations. *Montipora patula* has been reported to occupy shallow reef environments and reef flats, and is common in wave-swept environments but less tolerant of sediment-impacted areas. *Montipora patula/verrilli*'s habitat includes at least upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, and reef flats. The depth range is described as shallow reef flats down to 10 meters depth, with a report of 40 meters.

The public comments provided the following information. One public comment stated that a species that is highly consistent with Veron's description of *M. verrilli* has been reported from the Marianas. We gathered supplemental information, which stated that *M. patula* was considered endemic to the Hawaiian Islands and Johnston Atoll (Veron, 2000), but is now known to occur throughout the Hawaiian Islands, and also in the Line Islands, Marquesas, and Austral Islands (Veron, 2014). Veron (2014) reports *M. patula* as absent from Johnston Atoll, but this is an error as it is well known to occur there (Maragos and Jokiel, 1986); (Coles *et al.*, 2001); (Brainard *et al.*, 2005; Veron, 2000; Williams and Miller, 2012); (Lobel and K., 2008). Veron (2014) does not report on *M. verrilli*. Like *M. patula*, *M. verrilli* is reported from the Hawaiian Islands and Johnston Atoll (Veron, 2000), but is also reported from the Mariana Islands and Palau (Randall, 1995; Randall, 2003; Randall and Myers, 1983). Veron (2014) reports that *M. patula* is confirmed in five of his 133 Indo-Pacific ecoregions and strongly predicted in an additional two ecoregions.

*Montipora patula* is commonly observed deeper than 10 m throughout the Hawaiian Islands (Samuel Kahng, personal comm.), but its deepest depth range is not reported. The public comments and information we gathered provided nothing supplemental on *M. patula/verrilli*'s habitat and depth range.

#### Demographic Information

The SRR and SIR provided the following information on *M. patula/verrilli*'s abundance. *Montipora patula* and *M. verrilli* have been reported as sometimes common. *Montipora patula* is the most abundant of the three Hawaiian endemic (nominal) *Montipora* with overall statewide mean cover of 3.3 percent, making it the fourth most abundant coral in Hawai'i. *Montipora verrilli* is less abundant in Hawai'i.

Dollar and Grigg (2004) show substantial declines of *M. patula* on a subset of their transects over 12 years, but other transects within sites show high variability between surveys or similar cover between the beginning and end of the study.

The public comments provided the following information on this species' demography. One public comment stated that data from 79 monitoring sites in Hawaii from 1999 to 2012 suggest that *M. patula* and *M. verrilli* are experiencing different trajectories in growth and abundance. A second public comment stated that the SRR's characterization of *M. patula*'s populations as declining disregards public records of numerous long-term monitoring programs that have demonstrated its considerable abundance along the Hawaiian coast and its resistance to extreme conditions. A third public comment provided quantitative coral cover data from a variety of transects taken in Hawaii. *Montipora patula* often had the third, fourth, or fifth highest coral cover of any species. We gathered supplemental information, including Veron (2014), which while he did not conduct abundance surveys in Hawaii, describes the overall abundance of *M. patula* as "uncommon." *Montipora patula* is one of the most common reef-building corals in Hawaii. Jokiel *et al.* (2004) reported that *M. patula* has an overall statewide mean cover of 2.7 percent and the Hawaii Coral Reef Assessment and Monitoring Program (CRAMP) indicates that *M. patula* has an overall statewide mean cover of 3.3 percent (CRAMP, 2008b). Those mean cover percentages make *M. patula* the fourth most abundant coral in the main Hawaiian Islands. Fenner (2005) considered *M. patula* as one of the five most common corals in Hawaii. Grigg (1984) found that *M. patula* was the fifth most common coral in the main Hawaiian Islands. A species distribution model predicted that *M. patula* has the second highest coral cover of all reef-building coral species in the main Hawaiian Islands (Franklin *et al.*, 2013). *Montipora verrilli* has been reported to dominate deep, still water along with another *Montipora* species at Johnston Island (Jokiel and Tyler III, 1992) and *M. patula* is reported to be one of the two most common corals at Johnston Island (NOAA, 2006). In one study, *M. patula* was found at every one of the 11 stations at Johnston Island that were surveyed (Coles *et al.*, 2001). These three studies may refer to the same species.

The species has been monitored on some time-series transects in Hawaii.

Dollar and Grigg (2004) monitored coral cover over 12 and 20 year periods at three sites in Hawaii, each with multiple transects: a semi-enclosed embayment on Maui and two open coastal sites on Kauai and the Big Island. At the Maui site, overall live coral cover declined by approximately 33 percent from 1990 to 2002; *M. patula* cover declined from 13.8 to 8.2 percent of total live coral cover, and was the fourth most abundant coral at this site. At the Kauai site, overall live coral cover increased by approximately 30 percent from 1983 to 2002; *M. patula* increased from 24.9 to 36.0 percent of total live coral cover, and was the second most abundant coral at this site. At the Big Island site, overall live coral cover increased by approximately 50 percent from 1983 to 2002; *M. patula* increased from 0.7 to 3.3 percent of total live coral cover, and was the fourth most abundant coral at this site (Dollar and Grigg, 2004). Friedlander and Brown (2005) monitored coral cover for 12 years at 20 transects in Hanalei Bay, Kauai. Overall live coral cover increased by approximately 30 percent from 1993 to 2004, *M. patula* increased from approximately 50 to 60 percent of total live coral cover, and was the most abundant coral (Friedlander and Brown, 2005). In its public comment letter on the proposed rule, the National Park Service summarized data collected from 1999 to 2012 at 79 sites at different depths from the main Hawaiian Islands (exact locations not identified) showing that *M. patula* increased in live coral cover by approximately 2.3 percent over the 14 year period at all sites combined. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

#### Other Biological Information

The SRR and SIR provided the following information on *M. patula/verrilli's* life history. *Montipora patula* and *M. verrilli* are both documented as hermaphroditic broadcast spawners. Release of packaged egg and sperm bundles has been observed in the months of July through September at Coconut Island, Oahu, during two moon phases: new to first quarter, and full to third quarter. Although specific larval descriptions have not been published for this species, the larvae of all other *Montipora* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments

and information we gathered provided no supplemental biological information.

#### Susceptibility to Threats

To describe *M. patula/verrilli's* threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Montipora* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *M. patula/verrilli's* threats. *Montipora patula* is among the most bleaching-susceptible corals in the Northwestern Hawaiian Islands and may be moderately susceptible in the main Hawaiian Islands. What ultimately became known as the stress-tolerant zooxanthellae clade D was first documented in shallow-water *M. patula* in Hawai'i, though it also hosts clade C in deeper waters. Both nominal *M. patula* and *M. verrilli* are specifically noted with acute disease conditions (involving tissue loss/partial mortality) with high frequency of occurrence (over 20 percent of surveyed sites where the taxa was observed showed disease signs) and high prevalence (over seven percent in some sites) in the Northwestern Hawaiian Islands (Aeby, 2006). This author points out that the high prevalence sites had suffered severe bleaching in the previous year. *Montipora patula* may be less sediment tolerant than other *Montipora* species (Jokiel *et al.*, 2007), and it did disappear from survey stations in Pelekane Bay, Hawai'i between 1977 and 1996 as the bay became more impacted by sediment. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *M. patula/verrilli*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *M. patula/verrilli's* vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, and predation, and low vulnerability to sea-level rise, and collection and trade.

Public comments provided some supplemental information on *M. patula/verrilli's* threat susceptibilities. One public comment stated that in nearshore areas exposed to extremes of low salinity and temperature such as the eastern shore of the island of Hawaii where there are many streams and groundwater discharges, *M. patula* is one of the most common corals, sometimes nearly covering the entire reef surface. *Montipora patula* is one of the most common corals in harbors around the state of Hawaii, where it

tolerates elevated sediment loading and resuspension.

We gathered the following species-specific and genus-level information on this species' threat susceptibilities. *Montipora patula* has been rated as moderately or highly susceptible to bleaching and coral disease, but *M. verrilli* has not been rated as moderately or highly susceptible to bleaching and coral disease, however, these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Kenyon and Brainard (2006) report that *M. patula* was the most frequently bleached coral in Maro, Laysan, and Lisianski in the Northwestern Hawaiian Islands in 2004. At Pearl and Hermes reef, more than half of the *M. patula* colonies bleached, although more than half of the colonies of several other coral species also bleached. In a bleaching event in 1996, *M. patula* was found to have a moderate sensitivity to bleaching (Jokiel and Brown, 2004). At Kailua, Oahu, *M. patula* was observed to partly bleach every year for four years in April or May and October or September (Hoegh-Guldberg, 1995). *Montipora patula* colonies host multiple zooxanthellae clades, depending on location and depth. In Hawaii, colonies from different sites and depths had two different clades (LaJeunesse *et al.*, 2004a), and at Johnston Atoll, colonies from different sites and depths had four different clades, including the two found in the Hawaii colonies (Stat *et al.*, 2009).

In the main Hawaiian Islands, an outbreak of filamentous bacterial diseases began in 2012 on Kauai, and continued in 2013, heavily affecting the *Montipora* species on these reefs, including *M. capitata*, *M. flabellata*, and *M. patula* (Work, 2013). These *Montipora* species appear to be highly susceptible to these diseases when environmental conditions are degraded, especially the larger colonies (Thierry Work, personal comm.). It is unknown if these *Montipora* species are highly susceptible to these diseases when environmental conditions are not as degraded as they are on Kauai. With regards to sedimentation, the SRR referred to a study that concluded *M. patula* was more sensitive to sediment than other corals and another study that concluded *M. verrilli* was relatively resistant to sedimentation. No other species-specific information is available for the susceptibility of *M. patula/verrilli* to any other threat.

Based on genus-level and species-specific information described above, *M. patula/verrilli* likely is highly susceptible to ocean warming, likely has some susceptibility to disease, ocean

acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *M. patula/verrilli* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *M. patula/verrilli*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *M. patula/verrilli* occurs in eight Indo-Pacific ecoregions that encompass four countries' EEZs. The four countries are France (French Pacific Island Territories), Kiribati, Palau, and the United States (Guam, CNMI, Hawaii, PRIAs). The regulatory mechanisms relevant to *M. patula/verrilli*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (75 percent with none limited in scope), coral collection (100 percent with 25 percent limited in scope), pollution control (75 percent with 25 percent limited in scope), fishing regulations on reefs (100 percent with 25 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). All five regulatory mechanisms are very common for managing *M. patula/verrilli*, with only coral collection, pollution control, and reef fishing laws somewhat limited in scope.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *M. patula/verrilli* include its combined very narrow geographic distribution, restriction to shallow habitats, and its generic high susceptibility to a range of threats (bleaching, predation) and documented species-specific impacts from disease. No species characteristics were noted in the SRR that reduced expectations of extinction risk.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *M. patula/verrilli*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes coral reef ecoregions spanning an arc across the Pacific Ocean from the Mariana to Hawaiian to Austral Islands. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from low tide to more than 10 meters, possibly as deep as 40 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, and reef flats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its common and stable or increasing abundance in parts of its range, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a

large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *M. patula/verrilli* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *M. patula/verrilli* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *M. patula/verrilli*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Montipora patula/verrilli*'s distribution range is widespread, although disjointed and not continuous, from Palau to Hawaii to French Polynesia. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Montipora patula/verrilli* is one of the most abundant species in Hawaii, a major part of its range, and time-series studies of various sites around Hawaii since the 1980s seem to show stability in overall abundance trends in *M. patula*. The species' abundance

provides buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response;

(3) The depth range for *M. patula/verrilli* likely extends to 40 m depth, suggesting the possibility of depth refuges from ocean warming and other threats, and indicating a higher absolute area of potential occupancy within the species range;

(4) Many of the areas where *M. patula/verrilli* is found in the Pacific are remote and mostly uninhabited, reducing the likelihood of exposure to local sources of impacts that result from human activities; and

(5) All five major categories of protective regulatory mechanisms addressing local sources of threats are implemented by 75 to 100 percent of the countries within *M. patula/verrilli*'s range, with only three categories somewhat limited in scope.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *M. patula/verrilli* is not warranted for listing at this time under any of the listing factors.

#### Genus *Alveopora*

##### Genus Introduction

The family Poritidae consists of six genera: *Porites*, *Goniopora*, *Alveopora*, *Stylaraea*, *Poritipora*, and *Calathistes*.

*Alveopora* consists of 14 species, all occurring in the Indo-Pacific (Veron, 2000). Colonies are usually massive, branching, plating, or a combination. The SRR and SIR provided no genus-level introductory information on *Alveopora*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Alveopora*. The genus *Alveopora* is listed as having the highest bleaching response from the 17 included genera in the Indian Ocean. *Alveopora* had high bleaching in Guam in 1994 and South Africa in 2000, but had little bleaching or mortality in Palau in the 2001 event. Low-to-moderate bleaching of *Alveopora allingi* was observed in East Africa during the 1997–1998 event. A few disease reports for the genus *Alveopora* can be found in the Global Disease Database.

The public comments did not provide supplemental information on the threat susceptibilities of the genus *Alveopora*. We gathered supplemental information that provided the following. In Palau in 2000, *Alveopora* species had “relatively little bleaching and mortality.” Forty eight percent of all colonies of all species were bleached, and bleaching of different genera and species ranged from none to very high, but no quantitative results were reported for any *Alveopora* species (Bruno *et al.*, 2001). In Kenya in a bleaching event in 1998, all *Alveopora* colonies in the study sites were killed by mass bleaching (McClanahan *et al.*, 2001). In Mauritius in a bleaching event in 2004, *Alveopora* colonies had a bleaching index of 62, the second highest of the 32 genera recorded (McClanahan *et al.*, 2005a). In the western Indian Ocean, relative extinction risk scores for coral genera were calculated based on observed genus-level bleaching between 1998 and 2005. The index of extinction risk was proportional to the degree of bleaching, and inversely proportional to the abundance and number of reefs on which a taxon was found on. The index of extinction risk for *Alveopora* was the ninth highest out of 47 genera, with a score of 0.41 based on a scale of 0 to 1 with 1 being the score of the highest scoring genus (McClanahan *et al.*, 2007a). In Indonesia, colonies of *Goniopora* and *Alveopora* had a combined disease prevalence of about 0.3 percent, which was considered low (Haapkyla *et al.*, 2007).

##### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make

the following inferences about the susceptibilities of an unstudied *Alveopora* species to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. The studies reporting bleaching in the genus *Alveopora* reported a wide range of results, from high levels of bleaching to low levels of bleaching. There are a few reports of disease in *Alveopora* in the Global Disease database, and *Goniopora* and *Alveopora* had low combined disease prevalence in Indonesia. Thus, we conclude that *Alveopora* is likely to have some susceptibility to ocean warming and disease. Although there is no other genus-level or species-specific information on the susceptibilities of *Alveopora* species to ocean acidification, the SRR rated it as “medium-high” importance to corals. Thus, we conclude that an unstudied *Alveopora* species is likely to have some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Alveopora* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. Although there is no other genus-level or species-specific information on the susceptibilities of *Alveopora* species to sedimentation and nutrients, the SRR rated them as “low-medium” importance to corals. Thus we conclude that an unstudied *Alveopora* species is likely to have some susceptibility to sedimentation and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Alveopora* species is likely to have some

susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. Although there is no other genus-level or species-specific information on the susceptibilities of *Alveopora* species to collection and trade, there is no information suggesting they are not susceptible to these threats. Thus we conclude that an unstudied *Alveopora* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Alveopora* species is likely to have some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

### *Alveopora allingi*

#### Introduction

The SRR and SIR provided the following information on *A. allingi*'s morphology and taxonomy. Its morphology was described as colonies being encrusting or having short irregular lobes with rounded surfaces or being columnar. Its taxonomy was described as having no taxonomic issues, but being similar to *Alveopora catalai* and

*Alveopora marionensis*.

Public comments and information we gathered did not provide supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. allingi*, and a low level of species identification uncertainty. Veron (2014) states that *A. allingi* is distinctive and Veron (2000; 2014) considers the species valid, thus we consider it can be identified by experts and conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. allingi*'s distribution, habitat, and depth range. *Alveopora allingi* has a very broad distribution from the Red Sea and Indian Ocean to most of the Pacific Ocean. The SRR reported that *A. allingi*'s habitat is protected reef environments and its depth range is five to 10 m deep. Protected reef environments includes a large diversity of habitats, including lagoons, back-reef pools, leeward reefs, and others.

Public comments provided supplemental information on the distribution and habitat of *A. allingi*. A

public comment pointed out that in the Marianas, this species is restricted to depths greater than 60 meters. The four type specimens of *A. allingi* were dredged from Pago Pago harbor, all from a depth of 100 feet or more (Hoffmeister, 1925). We also gathered supplemental information, including Veron (2014), which reports that *A. allingi* is confirmed in 53 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 27. Thus, based on all the available information, *A. allingi*'s habitat includes lagoons, upper reef slopes, mid-slope terraces, lower reef slopes, and mesophotic areas in depths ranging from five to greater than 60 m.

#### Demographic Information

The SRR and SIR reported *A. allingi*'s abundance as usually uncommon.

Public comments did not provide supplemental information on the abundance of *A. allingi*. We gathered supplemental information, including Veron (2014), which reports that *A. allingi* occupied 1.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.27 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “uncommon,” and overall abundance was described as “usually uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. allingi*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi

*et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. allingi* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. allingi*'s life history. On high latitude reefs (28 to 29 degrees South) in the Houtman Abrolhos Islands, western Australia, two colonies of *A. allingi* were sampled before the main mass spawning nights in late March 1987. There was no indication of developed gametes, suggesting that this species does not participate in the mass spawning. Public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. allingi*'s threat susceptibilities, The SRR and SIR provided genus-level information for the effects on *Alveopora* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *A. allingi*'s threats. Low-to-moderate bleaching of *Alveopora allingi* was observed in East Africa during the 1997–1998 event. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. allingi*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. allingi*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide supplemental information on *A. allingi*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Alveopora allingi* has been rated as moderately or highly susceptible to bleaching but not to disease, but this rating is not based on species-specific data (2008). Based on the genus-level and species information described

above, *A. allingi* is likely to have some susceptibility to warming-induced bleaching, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibility of *A. allingi* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. allingi*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *A. allingi* occurs in 53 Indo-Pacific ecoregions that encompass 40 countries' EEZs. The 40 countries are Australia, Cambodia, China, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Japan, Jordan, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Mozambique, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, South Africa, Sri Lanka, Sudan, Taiwan, Tanzania, Timor-Leste, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (CNMI, Guam, American Samoa, PRIAs), Vietnam, and Yemen. The regulatory mechanisms relevant to *A. allingi*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentage of those countries whose regulatory mechanisms may be limited in scope are as follows: General coral protection (28 percent with five percent limited in scope), coral collection (60 percent with 25 percent limited in scope), pollution control (45 percent with eight percent limited in scope), fishing regulations on reefs (88 percent with 20 percent limited in scope), and managing areas for protection and conservation (95 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. allingi* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 25 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. allingi*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR states that the high bleaching rate is the primary known threat of extinction for *A. allingi*. It listed factors that reduce potential extinction risk including that *A. allingi* occupies a variety of habitat types and is broadly distributed both latitudinally and longitudinally in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. allingi*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean and the central Pacific, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from five to 60 meters. Its depth range moderates vulnerability to extinction over the foreseeable future because of lower irradiance in the deeper portion of its range, sharply reducing warming-induced bleaching. In addition, other threats usually occur at lower levels at mesophotic depths, such as sedimentation resulting from land-based sources of pollution. However, *A. allingi* colonies in mesophotic habitat may be affected by increasing acidification over the

foreseeable future, but the species also occurs in shallow depths less affected by acidification. Its habitat includes lagoons, upper reef slopes, mid-slope terraces, lower reef slopes, and mesophotic areas, moderating vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. allingi* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. allingi* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. allingi*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Alveopora allingi*'s distribution across the Red Sea, Indian Ocean and most of the Pacific Ocean is spread over a vast area. While some areas within its range are projected to be affected by

warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean and the central Pacific. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Alveopora allingi's* depth range down to 60 m and below includes depths that provide a refuge from ocean warming, and increase the absolute area of potential occupancy throughout the range of the species; and

(3) *Alveopora allingi's* total population size is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. allingi* is not warranted for listing at this time under any of the listing factors.

### *Alveopora fenestrata*

#### Introduction

The SRR and SIR provided the following information on *A. fenestrata's* morphology and taxonomy. Morphology was described as generally hemispherical with the surface divided into lobes, and the taxonomy was described as having no taxonomic issues, but it is similar to *Alveopora marionensis* and *Alveopora verrilliana*.

Public comments and information we gathered did not provide any new or supplemental information on morphology and confirmed that there are no known taxonomic problems for *A. fenestrata*, but that there is a moderate to high level of species identification uncertainty for this species. Veron (2014) states that *A. fenestrata* is easily confused with other *Alveopora* with similar growth form, but Veron (2000; 2014) considers the species valid, and we consider it can be identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. fenestrata's* distribution, habitat, and depth range. *Alveopora fenestrata* has a relatively broad distribution from the Red Sea and Indian Ocean to the central Pacific. Its habitat includes most coral reef environments, such as upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, reef flats, and lagoons, and its depth range is from three to 30 m.

Public comments provided the following information. *Alveopora fenestrata* occurs in Guam, but is not confirmed in the Northern Marianas. We gathered supplemental information, including Veron (2014) which reports that *A. fenestrata* is confirmed in 39 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 19.

#### Demographic Information

The SRR and SIR reported that *A. fenestrata's* abundance is uncommon.

Public comments provided the following information. *Alveopora fenestrata* is rare on Guam. We gathered supplemental information including Veron (2014) which reports that *A. fenestrata* occupied 1.98 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.29 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-

quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. fenestrata*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. fenestrata* occurs in many areas affected by these broad changes, and likely has some susceptibility to both local and global threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR did not provide supplemental species-specific biological information for *A. fenestrata*. Public comments provided no new or supplemental biological information.

#### Susceptibility to Threats

To describe *A. fenestrata's* threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Alveopora* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. fenestrata*. We interpreted threat

susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. fenestrata*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide supplemental information on *A. fenestrata*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' susceptibilities. *Alveopora fenestrata* has been rated as moderately or highly susceptible to bleaching but not to disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Darling *et al.* (2012) performed a biological trait-based analysis to categorize the relative tolerance of coral species to environmental stress and *A. fenestrata* was classified as a "stress-tolerant" species. There is no other species-specific information for the susceptibility of *A. fenestrata* to any threat. Based on the genus-level and species information described above, *A. fenestrata* is likely to have some susceptibility to warming-induced bleaching disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibility of *A. fenestrata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. fenestrata*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *A. fenestrata* occurs in 39 Indo-Pacific ecoregions that encompass 27 countries' EEZs. The 27 countries are Australia, Brunei, China, Egypt, Federated States of Micronesia, France (French Pacific Island Territories), Indonesia, Israel, Jordan, Kenya, Madagascar, Malaysia, Marshall Islands, Mauritius, Papua New Guinea, Philippines, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan, Taiwan, Tanzania, Timor-Leste, United States (CNMI, Guam, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *A. fenestrata*, first described as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope,

are as follows: General coral protection (33 percent with 11 percent limited in scope), coral collection (56 percent with 22 percent limited in scope), pollution control (48 percent with 11 percent limited in scope), fishing regulations on reefs (85 percent with 22 percent limited in scope), and managing areas for protection and conservation (100 percent with 11 percent limited in scope). The most common regulatory mechanisms in place for *A. fenestrata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 40 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less prominent regulatory mechanisms for the management of *A. fenestrata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that a high bleaching rate is the primary known threat of extinction for *A. fenestrata*. It listed factors that reduce potential extinction risk including occupying a range of depths and being broadly distributed both latitudinally and longitudinally in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. fenestrata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its

geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from three to 30 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, reef flats, and lagoons, moderating vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. fenestrata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. fenestrata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best

available information above on *A. fenestrata*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Alveopora fenestrata*'s distribution across approximately three quarters of the Indo-Pacific region is spread over a vast area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean and the central Pacific. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Alveopora fenestrata*'s depth range down to 30 m and below includes depths that provide a refuge from ocean warming, and increase the absolute area of potential occupancy throughout the range of the species; and

(3) *Alveopora fenestrata*'s total population size is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not

likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. fenestrata* is not warranted for listing at this time under any of the listing factors.

#### *Alveopora verrilliana*

##### Introduction

The SRR and SIR provided the following information on *A. verrilliana*'s morphology and taxonomy. Morphology was described as short irregularly dividing knob-like branches and the taxonomy was described as having no taxonomic issues. *Alveopora verrilliana* is similar to *Alveopora fenestrata*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. verrilliana*, but that there is a high level of species identification uncertainty for this species. Veron (2014) states that *A. verrilliana* is easily confused with other *Alveopora* with a similar growth form and it is impossible to confirm many citations of this species. However, Veron (2000; 2014) considers the species valid, and we consider it can be identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. verrilliana*'s distribution, habitat, and depth range. *Alveopora verrilliana*'s distribution is from the Red Sea to the central Indo-Pacific to most of the Pacific. Its habitat includes most coral reef environments, such as upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, reef flats, and lagoons, and its depth range is three to at least 40 meters depth, and possibly down to 80 meters (it is not certain that the identity of the coral at 80 meters has been verified).

Public comments provided the following supplemental information on *A. verrilliana*'s distribution, habitat and depth range. One public comment stated that *A. verrilliana* has been found in the Marianas on shallow fringing reef platforms at a depth between 1.5 and 2 meters deep, and a terrace at 17 meters deep. We gathered supplemental information, including Veron (2014), which reports that *A. verrilliana* is confirmed in 28 of his 133 Indo-Pacific

ecoregions, and strongly predicted to be found in an additional 30. One of the 30 strongly predicted ecoregions is the Main Hawaiian Islands (Veron, 2014), and may be based on reports that Hawaii is a similar type ecoregion. However, there are no reliable reports of the species being found in the Main Hawaiian Islands, in spite of many divers in the water observing coral species (Douglas Fenner, personal com.). Veron (2014)'s map indicates that the report(s) of this species from the Red Sea have also not been verified.

##### Demographic Information

The SRR and SIR reported *A. verrilliana*'s abundance as "uncommon." Public comments provided the following supplemental information on *A. verrilliana*'s abundance. One public comment stated that *A. verrilliana* is uncommon in the Marianas with only 10 to 12 colonies recorded so far. We gathered the following supplemental information on the abundance of *A. verrilliana*. Veron (2014) reports that *A. verrilliana* occupied 0.27 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.13 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare," and overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. verrilliana*, the overall decline in abundance ("Percent Population Reduction") was estimated at 34 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years

(Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. verrilliana* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. verrilliana*'s life history. *Alveopora verrilliana* is a hermaphroditic broadcast spawner. On temperate latitude reefs (28 to 29 degrees S) in the Houtman Abrolhos Islands, western Australia, seven of 12 colonies sampled had ripe gametes, and spawning was inferred during the time of mass spawning for this region. Public comments and information we gathered did not provide anything additional to the above-described biological information.

#### Susceptibility to Threats

To describe *A. verrilliana*'s threat susceptibilities, The SRR and SIR provided genus-level information for the effects on *Alveopora* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. verrilliana*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. verrilliana*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *A. verrilliana*'s threats. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Alveopora verrilliana* has been rated as moderately or highly susceptible to bleaching but not to disease, but this rating is not based on species-specific data (2008). There is no species-specific information for the exposure or susceptibility of *A. verrilliana* to any threat. Based on the genus-level and species information described above, *A. verrilliana* likely has some susceptibility to ocean warming, disease, acidification,

trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibility of *A. verrilliana* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. verrilliana*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *A. verrilliana* occurs in 28 Indo-Pacific ecoregions that encompass 23 countries' EEZs. The 23 countries are Australia, Brunei, Cambodia, China, Federated States of Micronesia, France (French Pacific Island Territories), Indonesia, Japan, Malaysia, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Solomon Islands, Taiwan, Thailand, Tonga, Tuvalu, United States (CNMI, Guam, American Samoa), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *A. verrilliana*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (30 percent with 4 percent limited in scope), coral collection (61 percent with 35 percent limited in scope), pollution control (39 percent with 13 percent limited in scope), fishing regulations on reefs (100 percent with 17 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *A. verrilliana* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat common for the species, but 35 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are much less common regulatory mechanisms for the management of *A. verrilliana*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR states

that the high bleaching rate is the primary known threat of extinction for *A. verrilliana*. It listed factors that reduce potential extinction risk including that *A. verrilliana* occupies a variety of habitat types and is broadly distributed both latitudinally and longitudinally in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. verrilliana*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many of the coral reef ecoregions in the western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from three to 40 meters, which moderates vulnerability to extinction over the foreseeable future because of lower irradiance in the deeper portion of its range, sharply reducing warming-induced bleaching. In addition, other threats usually occur at lower levels at mesophotic depths, such as sedimentation resulting from land-based sources of pollution. However, *A. verrilliana* colonies in mesophotic habitat may be affected by increasing acidification over the foreseeable future, but the species also occurs in shallow depths less affected by acidification. Its habitat includes most coral reef environments, such as upper reef slopes, mid-slopes, lower reef slopes, lower reef crests, reef flats, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on

local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its total abundance is unknown, and it is uncommon or rare. Its absolute abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule, using the determination tool formula approach, *A. verrilliana* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and wide depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. verrilliana* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. verrilliana*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Alveopora verrilliana*'s distribution across more than half of the Indo-Pacific region is spread over a vast area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species

range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Alveopora verrilliana*'s depth distribution down to 40 meters includes depths that provide a refuge from ocean warming, and increase the absolute area of potential occupancy throughout the range of the species; and

(3) *Alveopora verrilliana*'s total population size is at least millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. verrilliana* is not warranted for listing at this time under any of the listing factors.

#### Genus *Porites*

##### Genus Introduction

*Porites* colonies are flat (laminar or encrusting), massive, or branching. Massive colonies are spherical or hemispherical when small, and helmet or dome-shaped when large, and may be over five meters across (Veron, 2000). *Porites* is the third largest genus of reef building scleractinia, and Veron (2000) recognizes 52 species. This description of the *Porites* genus focuses on the Indo-Pacific, where most of the species occur.

The larvae of all *Porites* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The SRR and SIR provided no genus-level introductory information on *Porites*.

#### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Porites*. On the GBR and in the western Indian Ocean, massive *Porites* generally have moderate susceptibility to bleaching, while branching *Porites* generally have higher susceptibility to bleaching, comparable to *Pocillopora* and *Acropora*. For example, *Porites horizontalata* was a bleaching "loser" in Okinawa, disappearing after the 1998 event. Recent work comparing *P. lobata* from extreme lagoonal environments with individuals from more benign forereef habitats in American Samoa indicates that thermal history of these corals plays a large part in their reaction to thermal stress.

The SRR reported that a study that looked at 328 colonies of massive *Porites* from 69 reefs of the GBR found a decline in calcification of 14.2 percent since 1990, predominantly because extension declined by 13.3 percent. This is similar to the estimates of a global decline in aragonite saturation state of 16 percent since the beginning of global industrialization. The study agreed with earlier, more limited work on *Porites* on the GBR and in laboratory and mesocosm experiments that showed declines in calcification with reduced aragonite saturation state in *P. cylindrical*, *P. compressa*, and *P. lutea* adults, and *P. astreoides* juveniles. Acidification has not been found to interfere with settlement of larvae in *P. astreoides* in the Caribbean.

The SRR reported several studies showing subacute (lesions resulting in slow progressive tissue loss) tissue loss, black band disease, and endolithic hypermycosis in *Porites*. The SIR reported that the genus *Porites* had the highest prevalence of disease throughout Guam; however, it may have also been a function of the fact that *Porites* corals are also the most common. Likewise, in a study from Hawaii, with 12 diseases recorded among three coral genera, *Porites* was shown to have the highest prevalence of disease. *Porites* was also shown to have severe damage as a result of high disease prevalence of black-band disease in Southeastern India.

The SRR reported that *Porites* is susceptible to crown-of-thorns seastar (*Acanthaster planci*) and corallivorous

snail predation, including predation of *Coralliphilia violacea* on both massive and branching forms. Massive *Porites* are susceptible, but not a preferred prey, of the predatory asteroid *Culcita novaeguineae*, and the butterflyfish *Chaetodon unimaculatus*. *Porites* is intermediate for its sediment tolerance in the western Indian Ocean. In contrast, *Porites* is often found in relatively turbid waters in Asia and the eastern Pacific and were considered sediment tolerant. About 25,000–50,000 pieces of *Porites* spp. per year are traded.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Porites*. We gathered supplemental information that provided the following. Thermal stress was studied by Gleason (1993), who reported that *Porites* was little affected by bleaching in Moorea, French Polynesia. Bruno *et al.* (2001) reported that in Palau in 2000, four different species of *Porites* ranged from low-moderate levels of bleaching to very high-moderate, and ranged from low-moderate mortality to high mortality. Done *et al.* (2003b) reported bleaching levels in seven species of *Porites* and one morphological group (massive) of *Porites*. Individual species ranged from eight to 33 percent affected by bleaching. The two least affected species (*P. cylindrica* and *P. annae*) were branching and the most affected was massive (*P. vaughani*), though it had a low mortality. Generally, massive *Porites* were affected more than average. The species with the greatest mortality was a species with columns and plates (*P. rus*) though another species (*P. lichen*) with columns and plates had a mortality rate nearly as low as the lowest mortality species, and another species with columns (*P. heronensis*) had high bleaching (Done *et al.*, 2003b).

Pandolfi *et al.* (2011) reported that massive species of *Porites* bleached about average for genera in Kenya and Australia in 1998. A study that monitored the impacts of the 1998 and 2010 bleaching events on coral in Japan (van Woesik *et al.*, 2011) reported that one species of branching *Porites* was neither a winner or a loser (increasing from 1.4 percent cover to four percent and then decreasing to 0.9 percent), and six species of branching *Porites* were long-term losers (decreasing to 0 percent cover and staying there). Vargas-Angel *et al.* (2011) reported that *Porites* had a fairly low percentage of bleaching on Howland and Baker islands in the U.S. Pacific, with 16.1 percent on Baker and 24.6 percent on Howland. *Porites* was the ninth most-bleached genus out of 14

genera, and had 32 percent as much bleaching as the most bleached genus (Vargas-Angel *et al.*, 2011). *Porites* in Okinawa, Japan, experienced no decrease in populations following the 1998 and 2010 mass bleaching episodes. Okinawa has turbid waters from runoff increased by human activities (Hongo and Yamano, 2013).

In areas of Papua New Guinea, where volcanic carbon dioxide bubbling produced pH equal to that predicted for 2100, massive *Porites* dominated the community, indicating they are more resistant to low pH than other corals (Fabricius *et al.*, 2011). Massive *Porites* growth rates in bays in Palau, with pH approaching that predicted for 2100 and aragonite saturation equal to that predicted for 2100, was similar to colonies in water with current mean pH and aragonite saturation (Shamberger *et al.*, in press).

Raymundo *et al.* (2005) reported that *Porites* had the highest levels of disease in the Philippines, where only rarely did other genera show disease. Individual species of *Porites* differed greatly in the prevalence of disease, with zero prevalence in about half of the species, and a wide range of prevalence in the others. Further, there was no consistent difference between massive and branching species: branching species displayed the entire range of prevalence; massive *Porites* having relatively high prevalence, though not as high as three branching species; and one massive *Porites* (*P. evermanni*) having zero prevalence (Raymundo *et al.*, 2005). *Porites* had the lowest prevalence of disease (0.025 percent) of the only five genera with diseases recorded in American Samoa. *Porites* tissue loss was found at 15 percent of sites compared to 71 percent of sites for *Acropora* white syndrome, the most common disease (Fenner and Heron, 2008). In another study in American Samoa, *Porites* had the third highest level of prevalence of any genus, with a prevalence of 0.11 percent (Aeby *et al.*, 2008). Growth anomalies are occasional on massive *Porites* in backreef pools on Ofu, American Samoa but less common on reef slopes in American Samoa. Growth anomalies are abundant on one color morph of *Porites cylindrica* in one small area of one back reef pool in Tutuila, American Samoa, but not on another color morph. A white disease that is rare on Tutuila, killed all *Porites rus* colonies (about 50) in front of Vaoto Lodge, Ofu, American Samoa. What appears to possibly be the same disease is killing all yellow massive *Porites* in the Hurricane House back reef pool on Ofu, American Samoa (Fenner, 2013b). In Guam, *Porites* had by far the

highest prevalence, with 6.7 percent of colonies having disease (Myers and Raymundo, 2009). *Porites* was tied for the second highest disease prevalence of 12 genera in New Caledonia, with 0.7 percent of colonies showing disease (Tribollet *et al.*, 2011). *Porites* massive was tied for third highest disease prevalence of 35 taxa in Indonesia, with 1.5 percent prevalence. *Porites* branching had the 14th highest disease prevalence of 35 taxa in Indonesia, with 0.25 percent of colonies showing disease. Other *Porites* had no disease in Indonesia (Haapkyla *et al.*, 2007).

Predation was studied by De'ath and Moran (1998), who reported that *Porites* was the least preferred prey of crown-of-thorns starfish out of the 10 most common genera on 15 reefs in the GBR. *Porites* species are relatively less susceptible to the effects of land-based sources of pollution than many other reef-building corals. *Porites* species are heavily collected and widely traded internationally. There is no information on the effects of fishing, sea-level rise, or any other threat to *Porites* species.

#### Genus Conclusions

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Porites* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. Most studies reported moderate to high levels of bleaching in *Porites*, but one study reported low levels and some individual species had low levels. In three studies, branching species showed higher levels of bleaching than massive species, and one study showed the reverse. Generally, *Porites* as a whole has moderate to high susceptibility to ocean warming. However, different species of *Porites* have a wide range of susceptibilities to ocean warming, thus we conclude that an unstudied *Porites* species has some susceptibility to ocean warming. Most studies found high levels of disease in *Porites*, but one study found low levels. We conclude that an unstudied *Porites* species has some susceptibility to disease. Several studies reported that calcification declined with decreasing pH in short term experiments, but massive *Porites* are common and have normal growth rates in natural areas of low pH. We

conclude that *Porites* has some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Porites* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. *Porites* is reported to have intermediate to high sediment tolerance. Thus we conclude that an unstudied *Porites* has some susceptibility to sedimentation. Although there is no genus-level or species-specific information on the susceptibilities of *Porites* species to nutrients, the SRR rated it as “low-medium” importance to corals. Thus, we conclude that an unstudied *Porites* species has some susceptibility to nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Porites* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. The only study of predation reporting on *Porites* indicated it was a not a preferred prey item of crown-of-thorns starfish. Thus, we conclude that *Porites* has a low susceptibility to predation. *Porites* species are heavily collected and widely traded internationally. Thus we conclude that *Porites* has some susceptibility to collection and trade.

In conclusion, an unstudied *Porites* species is likely to have some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, and collection and trade, and low susceptibility to predation.

#### *Porites horizontalata*

##### Introduction

The SRR and SIR provided the following information on *P.*

*horizontalata*'s morphology and taxonomy. Morphology was described as composites of encrusting plates and contorted fused branches. With respect to taxonomy, *Porites* is known to be morphologically plastic and multiple sympatric species frequently exhibit intergradation of skeletal characteristics. The results of a study of genetics of other *Porites* species found that genetics did not correspond well with *Porites* species based on morphology. The laminar parts of colonies of *P. horizontalata* resemble *Porites vaughani*, the branching parts may have corallites arranged in a star-like pattern like *Porites rus*, and the corallite features are most similar to *Porites eridani*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *P. horizontalata*, and that there is a moderate level of species identification uncertainty for this species. Veron (2000; 2014) states that *P. horizontalata* is easily confused with *P. rus*, but the species can be identified by experts (Fenner, 2014b), thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *P. horizontalata*'s distribution, habitat, and depth range. *Porites horizontalata*'s distribution is from the central Indian Ocean to the central Indo-Pacific and central Pacific. The SRR reported that *P. horizontalata*'s habitat is shallow reef environments, and the depth range is from five to 20 m, though it is also known to range into deep water. *Porites horizontalata* is uncommon in Guam and found in deeper quiet waters.

Public comments did not provide any new or supplemental information on *P. horizontalata*'s distribution. We gathered supplemental information including Veron (2014), which reports that *P. horizontalata* is confirmed in 28 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 13. Supplemental information on the depth range of *P. horizontalata* in American Samoa indicates it is from about 10 m to at least 30 m deep, and it has been observed at 20 to 30 m of depth in New Caledonia, where it appears much as it does in American Samoa in similar locations (D. Fenner, personal comm.). Thus, based on all the available information, *P. horizontalata*'s habitat includes at least

upper reef slopes, mid-slope terraces, lower reef crests, and lagoons in depth ranging from five to 30 m depth.

##### Demographic Information

The SRR and SIR provided the following information on *P. horizontalata*'s abundance. *Porites horizontalata* has been reported as sometimes common. Public comments did not provide any new or supplemental information on *P. horizontalata*'s abundance. We gathered supplemental information including Veron (2014) and Richards *et al.* (2008). Veron (2014) reports that *P. horizontalata* occupied 4.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.62 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “uncommon,” and overall abundance was described as “sometimes common in isolated habitats.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *P. horizontalata*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 37 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. horizontalata* occurs in many areas affected by these broad changes, and that it likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50

to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *P. horizontalata*'s life history. *Porites horizontalata* is a gonochoric broadcast spawner. Although specific observations have not been published for this species, the larvae of all other *Porites* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *P. horizontalata*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Porites* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR also provided the following species-specific information on *P. horizontalata*'s threats. *Porites horizontalata* was a bleaching "loser" in Okinawa, disappearing after the 1998 event. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. horizontalata*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *P. horizontalata*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of reef fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Several public comments provided supplemental information on *P. horizontalata*'s threat susceptibilities. One public comment stated that the Loya (2001) study of the effects of bleaching in Okinawa, which reported *P. horizontalata* as a loser, did not actually directly observe bleaching but rather looked at before and after abundances and deduced that species had or had not suffered from bleaching. It also stated that the sampling effort was small and the changes in low abundances may not even have been statistically significant. The comment suggests reducing the ocean warming component for this species in the determination tool to moderate to low (2.5) or to low (3). Another public comment stated that a published study

(Goreau *et al.*, 1972) as well as observations on Guam suggest that *Porites* species in the subgenus *Synaraea* are among the least-preferred prey of the crown-of-thorns starfish. The comment stated that other studies (Colgan, 1987; Pratchett, 2007) suggest that *Porites* species in general are among the least preferred prey of crown-of-thorns. The comment further stated that workers on Guam have never seen crown-of-thorns predation on *P. horizontalata* and suspect that this species is among the least preferred prey of crown-of-thorns. The comment suggests changing the predation susceptibility to low (3) or moderate to low (2.5) in the determination tool. A third comment suggested *P. horizontalata* be considered a "Synaraea" species instead of a branching *Porites* species. The common *Synaraea* species *Porites rus* has bleaching levels that are lower than both *Porites* branching and *Porites* massive corals. *Porites horizontalata* is within the *Synaraea* sub-genus and has not been observed to bleach in Guam to date.

We gathered the following supplemental species-specific information on susceptibility to threats for *P. horizontalata*. This species has been rated as moderately or highly susceptible to bleaching and disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). *Porites horizontalata* was found to be a long term loser in Japan following bleaching events (decreasing from 1.2 percent cover to zero and staying there) (van Woesik *et al.*, 2011). *Porites horizontalata* had the ninth highest disease prevalence of 21 species of *Porites* in the Philippines. *Porites horizontalata* had a prevalence of 4, which was 20 percent of the prevalence of the species with the highest prevalence (Raymundo *et al.*, 2005). There is no species-specific information for the susceptibility of *P. horizontalata* to any other threat. Based on information provided in the *Porites* genus description and the species-specific information above, *P. horizontalata* likely has some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, and collection and trade, and low susceptibility to predation. The available information does not support more precise ratings of the susceptibilities of *P. horizontalata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific

information on regulatory mechanisms or conservation efforts for *P. horizontalata*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *P. horizontalata* occurs in 28 Indo-Pacific ecoregions that encompass 25 countries' EEZs. The 25 countries are Brunei, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Japan, Malaysia, Marshall Islands, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Solomon Islands, Taiwan, Thailand, Timor-Leste, Tonga, Tuvalu, United States (CNMI, Guam, American Samoa, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *P. horizontalata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (28 percent with 4 percent limited in scope), coral collection (64 percent with 40 percent limited in scope), pollution control (36 percent with 12 percent limited in scope), fishing regulations on reefs (96 percent with 16 percent limited in scope), and managing areas for protection and conservation (96 percent with 4 percent limited in scope). The most common regulatory mechanisms in place for *P. horizontalata* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat utilized for the species, but 40 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are less prominent regulatory mechanisms for the management of *P. horizontalata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *P. horizontalata* include the fairly low tolerance to thermal stress and susceptibility to acidification based on genus-level information. It listed factors that reduce potential extinction risk including the

species' broad distribution and the low predation susceptibility of the genus.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *P. horizontalata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many of the coral reef ecoregions in the central Indo-Pacific, and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future including the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from five to 30 meters, and has been found deeper. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slope terraces, lower reef crests, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large

number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. horizontalata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *P. horizontalata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *P. horizontalata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Porites horizontalata*'s distribution across the central Indo-Pacific and central Pacific Ocean is spread over a vast area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Porites horizontalata*'s absolute abundance is at least tens of millions of colonies, which provides buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and

Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future as global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *P. horizontalata* is not warranted for listing at this time under any of the listing factors.

#### *Porites napopora*

##### Introduction

The SRR and SIR provided the following information on *P. napopora*'s morphology and taxonomy. Morphology was described as broad basal plates with irregular clumps of tapered irregularly fused branches. *Porites* is known to be morphologically plastic and multiple sympatric species frequently exhibit intergradation of skeletal characteristics. The results of a study of the genetics did not correspond well with the *Porites* species based on morphology. *Porites napopora* is similar to *P. nigrescens* and *P. negrosensis*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, but did confirm that there is moderate taxonomic uncertainty for *P. napopora* and a moderate level of species identification uncertainty. Veron (Veron, 2014) states that *P. napopora* is distinctive, and *P. napopora* can be identified by experts (Fenner, 2014b), thus we conclude that the distribution and abundance information described below for this

species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *P. napopora*'s distribution, habitat, and depth range. The SRR and SIR described *P. napopora*'s distribution as the Coral Triangle plus Micronesia and the Marianas Islands. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons, and the depth range as three to 15 meters.

Public comments did not provide any new or supplemental information on *P. napopora*'s distribution. We gathered supplemental information including Veron (Veron, 2014) which provides an updated, much more detailed range map for this species than the maps used in the SRR. Veron reports that this species is confirmed in 13 of his 133 Indo-Pacific ecoregions, and is strongly predicted to be found in an additional 13.

#### Demographic Information

The SRR and SIR provided the following information on *P. napopora*'s abundance. *Porites napopora* has been reported as sometimes common.

Public comments did not provide any new or supplemental information on *P. napopora*'s abundance. We gathered supplemental information including Veron (Veron, 2014), which reports that *P. napopora* occupied 2.6 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.79 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was described as "sometimes common in isolated habitats." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *P. napopora*, the overall decline in abundance ("Percent Population Reduction") was estimated at 33 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 15 percent in the study. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are

highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szamant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. napopora* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *P. napopora*'s life history. Although specific observations have not been published for this species, the larvae of all other *Porites* species studied contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *P. napopora*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acropora* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. napopora*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *P. napopora*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *P. napopora*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat

susceptibilities. *Porites napopora* has been rated as moderately or highly susceptible to disease but not to bleaching, but this rating is not based on species-specific data (2008). With regard to disease, *P. napopora* had the 13th highest disease prevalence of 21 species of *Porites* in the Philippines. *Porites napopora* had a prevalence of 0.2, which was one percent of the prevalence of the species with the highest prevalence (Raymundo *et al.*, 2005). There is no species-specific information for the susceptibility of *P. napopora* to any other threat. Based on information provided in the *Porites* genus description above, *P. napopora* is predicted to have some susceptibility to ocean warming, disease, acidification, and likely has some susceptibility to trophic effects of fishing, sedimentation, nutrients, sea-level rise, and collection and trade. Genus-level information indicates this species has low susceptibility to predation.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *P. napopora*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *P. napopora* occurs in 13 Indo-Pacific ecoregions that encompass 10 countries' EEZs. The 10 countries are Brunei, China, Federated States of Micronesia, Indonesia, Japan, Malaysia, Philippines, Taiwan, Timor-Leste, and Vietnam. The regulatory mechanisms relevant to *P. napopora*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (30 percent with none limited in scope), coral collection (60 percent with 30 percent limited in scope), pollution control (30 percent with 10 percent limited in scope), fishing regulations on reefs (100 percent with 30 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *P. napopora* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat utilized for the species, but 30 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are less prominent regulatory

mechanisms for the management of *P. napopora*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *P. napopora* include the species' distribution that is restricted to the western Pacific and the fairly low tolerance to thermal stress and susceptibility to acidification based on genus-level information. It listed factors that reduce potential extinction risk including its high tolerance of sediment stress and turbid water, and low predation susceptibility of the genus.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *P. napopora*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited to parts of the Coral Triangle and the western equatorial Pacific Ocean. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range is down to 15 meters. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is

generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. There is not enough information about its abundance to determine if it moderates or exacerbates extinction: It is uncommon overall but common in parts of its range, and has at least millions of colonies, but the great majority of the population is within an area expected to be severely impacted by threats over the foreseeable future.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. napopora* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); narrow overall distribution (based on moderate geographic distribution and shallow depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we did not change the listing determination for *P. napopora*. Based on the best available information provided above on *P. napopora*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Porites napopora* is susceptible to warming induced bleaching (ESA Factor E), disease (C), trophic effects of fishing (A), and nutrients (A, E). These threats are expected to continue and worsen into the future. In addition, existing regulatory mechanisms to address global threats that contribute to extinction risk for this species are inadequate (D); and

(2) *Porites napopora*'s distribution is constrained mostly to the Coral Triangle and western equatorial Pacific, which is projected to have the most rapid and

severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the western equatorial Pacific that suggest future ocean warming events may be more severe than average in this part of the world. In addition, the species has a depth distribution of three to 15 m. Such a geographic and depth distribution is likely to experience severe and increasing threats, indicating that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future.

The combination of these characteristics and future projections of threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *P. napopora*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *P. napopora*'s distribution is restricted mostly to the Coral Triangle, which increases its extinction risk as described above, its habitat includes shallow reef environments, which describes a variety of reef zones and habitat types in the coral reef ecosystem. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that compensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) *Porites napopora*'s absolute abundance is likely at least millions of colonies and is described as "sometimes common in isolated habitats" providing areas of localized abundance which allows for variation in the responses of individuals to threats to play a role in moderating vulnerability to extinction for the species to some degree, as described in more detail in the Corals and Coral Reefs section. There is no evidence of compensatory processes such as reproductive failure from low density of reproductive individuals and genetic

processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *P. napolopora*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Porites nigrescens*

##### Introduction

The SRR and SIR provided the following information on *P. nigrescens*' morphology and taxonomy. The morphology was described as branching, sometimes with an encrusting base, and concave calices give the surface a pitted appearance. *Porites* is known to be morphologically plastic and multiple sympatric species frequently exhibit intergradation of skeletal characteristics. The results of a genetics study did not correspond well with the *Porites* species based on morphology. *Porites nigrescens* is similar in appearance to *Porites cylindrica*.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there is moderate taxonomic uncertainty for *P. nigrescens* and that there is a moderate level of species identification uncertainty for this species. Veron (2014) states that *P. nigrescens* is easily distinguished from other branching *Porites*, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *P. nigrescens*'

distribution, habitat, and depth range. The SRR and SIR described *P. nigrescens*' distribution as occurring from the Red Sea and east Africa to the central Pacific. Its habitat includes coral reef environments protected from wave action, including at least upper reef slopes, mid-slopes, lower reef slopes, and lagoons, and its depth range as 0 to 20 meters.

The public comments provided information that *P. nigrescens* is widely distributed in all Indonesian waters. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 56 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 18.

##### Demographic Information

The SRR and SIR provided the following information on *P. nigrescens*' abundance. *Porites nigrescens* has been reported as sometimes common. Where found, it can be a part of a locally abundant branching poritid assemblage.

The public comments and information we gathered provided supplemental information on *P. nigrescens*' abundance. One public comment stated that *P. nigrescens* is very abundant in all Indonesian waters. We gathered supplemental information, including Veron (2014), which reports that *P. nigrescens* occupied 29.05 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 2.01 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "very common." Overall abundance was described as "sometimes common." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *P. nigrescens*, the overall decline in abundance ("Percent Population Reduction") was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent in the study. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of

context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by harder coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. nigrescens* occurs in many areas affected by these broad changes, and that it is likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species specific information.

##### Other Biological Information

The public comments and information we gathered did not provide any new or supplemental biological information on *P. nigrescens*.

##### Susceptibility to Threats

To describe *P. nigrescens*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Porites* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. nigrescens*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *P. nigrescens*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, and low vulnerability to sedimentation, sea-level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *P. nigrescens*' threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Porites nigrescens* has not been rated as moderately or highly susceptible to bleaching, but this rating is not based on species-specific data (2008). *Porites nigrescens* appears to have high susceptibility to thermal stress and warming-induced bleaching. *Porites nigrescens* had high bleaching rates in East Africa in 1998 (Obura, 2001) and Palau in 2000 (Bruno *et al.*, 2001). In East Africa, 99 percent of *P. nigrescens* colonies were affected by bleaching at the peak of bleaching in

1998 in Kenya, Tanzania, Mozambique, and Madagascar. This was the third-most affected species out of 14 species, and was affected 99 percent as much as the most affected species. At the end of bleaching, 87 percent of colonies were dead, which was the fifth-highest mortality species, and 94 percent of the mortality level of the highest mortality species (Obura, 2001). In Palau in 2000, *P. nigrescens* had very high to moderate bleaching, and very high mortality. Of all *P. nigrescens* colonies at the study site, 48 percent bleached, and bleaching of different genera and species ranged from none to very high, with mortality from zero to near 100 percent (Bruno *et al.*, 2001). Loya *et al.* (Loya *et al.*, 2001) reported that *P. nigrescens* was a “loser” in a 1998 bleaching event in Japan where it went down to zero abundance and cover (Loya *et al.*, 2001).

*Porites nigrescens* has been rated as moderately or highly susceptible to disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Raymundo *et al.* (2005) reported *P. nigrescens* had the seventh-highest disease prevalence of 21 species of *Porites* in the Philippines. *Porites nigrescens* had a moderate level of disease prevalence relevant to the other coral species in the study. No other species-specific information is available for the susceptibility of *P. nigrescens* to any other threat.

Based on species-specific and genus-level information above, *P. nigrescens* is likely highly susceptible to ocean warming and also likely has some susceptibilities to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *P. nigrescens* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *P. nigrescens*. Public comments were critical of that approach, and we therefore attempt to analyze regulatory mechanisms and conservation efforts on a species basis, where possible, in this final rule. Records confirm that *P. nigrescens* occurs in 56 Indo-Pacific ecoregions that encompass 43 countries' EEZs. The 43 countries are Australia, Brunei, Cambodia, China, Djibouti, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Japan, Kenya, Kiribati, Madagascar, Malaysia,

Marshall Islands, Mauritius, Mozambique, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Somalia, South Africa, Sri Lanka, Taiwan, Tanzania, Thailand, Timor-Leste, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (American Samoa, PRIAs), Vanuatu, Vietnam, and Yemen. The regulatory mechanisms available to *P. nigrescens*, described first as a percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (28 percent with 7 percent limited in scope), coral collection (56 percent with 28 percent limited in scope), pollution control (35 percent with 7 percent limited in scope), fishing regulations on reefs (95 percent with 23 percent limited in scope), and managing areas for protection and conservation (93 percent with 5 percent limited in scope). The most common regulatory mechanisms in place for *P. nigrescens* are reef fishing regulations and area management for protection and conservation. Coral collection laws are somewhat utilized but some are limited in scope and may not provide substantial protection for *P. nigrescens*. General coral protection and pollution control laws are much less prominent regulatory mechanisms for the management of *P. nigrescens*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *P. nigrescens* include the fairly low tolerance to thermal stress and susceptibility to acidification impacts in the genus. It listed factors that reduce potential extinction risk including the species' broad distribution, the high tolerance of sediment stress and turbid water, and low disease and predation susceptibility of the genus.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available

information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *P. nigrescens*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is down to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef slopes, and lagoons protected from wave action. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. nigrescens* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA

Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *P. nigrescens* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *P. nigrescens*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Porites nigrescens*' distribution from the Red Sea and east Africa across most of the Pacific Ocean is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Porites nigrescens*' absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of

these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *P. nigrescens* is not warranted for listing at this time under any of the listing factors.

#### Genus *Pachyseris*

##### Genus Introduction

The family Agaricidae includes six genera, *Agaricia* (Caribbean only), *Leptoseris*, *Pavona*, *Pachyseris*, *Gardineroseris*, and *Coeloseresis*. *Pachyseris* contains four species, all in the Indo-Pacific. *Pachyseris* species are foliose, and one species can produce short columns or branches. The SRR and SIR provided no genus-level introductory information on *Pachyseris*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Pachyseris*. A series of studies reported that *Pachyseris* experiences variable but high levels of bleaching, though in some places it may be bleaching tolerant. *Pachyseris*' high bleaching rate and relative rarity may give it a relatively high extirpation risk in the western Indian Ocean. Trade in this genus is relatively high.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Pachyseris*. We gathered supplemental information that provided the following details. *Pachyseris* had a bleaching index of 8.3 for eight countries in the western Indian Ocean in 1998–2005, which was 33rd highest of the 45 genera recorded, and 20 percent of the highest value. As a genus, its moderate bleaching rate combined with relative rarity may give it a relatively high extirpation risk in the western Indian Ocean (McClanahan *et*

*al.*, 2007a). Done *et al.* (2003b) reported that overall bleaching rates for two species of *Pachyseris* were 15 percent and 38 percent on the GBR in 2002, which were the seventh and third highest levels of bleaching out of 16 species of Agariciids. There is no information available on the effects of any other threat for *Pachyseris*.

##### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Pachyseris* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. *Pachyseris* has a variable level of susceptibility to bleaching, with most reports of bleaching being moderate to high. Thus, we conclude that an unstudied *Pachyseris* species is likely to have high susceptibility to ocean warming. Although there is no other genus-level or species-specific information on the susceptibilities of *Pachyseris* species to disease and ocean acidification, the SRR rated them as “high” and “medium-high” importance to corals, respectively. Thus, we conclude that an unstudied *Pachyseris* species is likely to have some susceptibility to disease and ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Pachyseris* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. Although there is no genus-level or species-specific information on the susceptibilities of *Pachyseris* species to sedimentation and nutrients, the SRR rated them as “low-medium”

importance to corals. Thus, we conclude that an unstudied *Pachyseris* species is likely to have some susceptibility to sedimentation and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Pachyseris* species is likely to have some susceptibility to sea-level rise. Although there is no genus-level or species-specific information on the susceptibilities of *Pachyseris* species to predation, there is no information suggesting they are not susceptible to this threat. Thus, we conclude that an unstudied *Pachyseris* species has some susceptibility to predation. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. Because the available general information suggests that collection and trade of *Pachyseris* species is relatively high, we conclude an unstudied *Pachyseris* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Pachyseris* species is likely to have high susceptibility to ocean warming, and some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, predation, sea-level rise, and collection and trade.

### *Pachyseris rugosa*

#### Introduction

In The SRR and SIR provided the following information on *P. rugosa*'s morphology and taxonomy. Morphology was described as colonies that are upright, irregular, fused, bifacial plates, and taxonomy was described as having no taxonomic issues, but being similar to *Pachyseris gemmae* and *Pachyseris involuta*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *P. rugosa*, and a low level of species identification uncertainty. Veron (2014) states that *P. rugosa* is very distinctive and Veron (2000; 2014) considers the species valid, and we consider it can be identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *P. rugosa*'s

distribution, habitat, and depth range. The SRR and SIR described *P. rugosa*'s distribution as from the Red Sea and east Africa to the central Pacific. Regarding habitat, the SRR and SIR stated that *P. rugosa* may develop into large mound-shaped colonies in shallow water but smaller colonies occur in a wide range of habitats including those exposed to strong wave action. It is associated with fine-grained sediments on the Great Barrier Reef, and could be an indicator of quiet water or a moderate energy environment. Thus, its habitat includes at least upper reef slopes, mid-slopes, and lagoons. Its depth range is from five to 20 meters, and it may be excluded from shallow environments by excess light.

Public comments did not provide any new or supplemental information on *P. rugosa*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 57 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 17.

#### Demographic Information

The SRR and SIR reported *P. rugosa*'s abundance as common.

Public comments did not provide any new or supplemental information on *P. rugosa*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *P. rugosa* occupied 23.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.45 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “common,” and overall abundance was also described as “common.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *P. rugosa*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on

small scales that can be easily taken out of context, thus quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. rugosa* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *P. rugosa*'s life history. *Pachyseris rugosa* is a gonochoric broadcast spawner. This species contains clade C zooxanthellae, with a predominance of clade C3h in areas of greater temperature or turbidity. Public comments and information we gathered added no new or supplemental information to the above-described biological information.

#### Susceptibility to Threats

To describe *P. rugosa*'s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Pachyseris* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *P. rugosa*'s threats. *Pachyseris rugosa* is vulnerable to a ciliate disease skeletal eroding band. Although overall disease presence was low during a survey in Indonesia, the black-band progressed across *P. rugosa* at an average rate of 0.63cm/d. Mass mortality of this species on the GBR has been attributed to crown of thorns starfish, although predation was not observed directly. *Pachyseris rugosa* has suffered high partial mortality as a result of dredging, but its branching structure should make it an efficient sediment-rejecter. The species disappeared in Jakarta Bay between 1920 and 2005, which was attributed to decreased water quality from coastal development. *Pachyseris rugosa* experiences substantial export, averaging 1195 specimens annually from 1991 to 2008, decreasing in 1997–2003, but returning to 2085 per year in

2004–2008. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. rugosa*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *P. rugosa*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, and trophic effects of fishing, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *P. rugosa*'s susceptibility to threats. We gathered the following supplemental species-specific and genus-level information on this species' threat susceptibilities. *Pachyseris rugosa* has been rated as moderately or highly susceptible to bleaching but not disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). With regard to thermal stress, 15 percent of *P. rugosa* colonies were affected by bleaching on the GBR in 2002. The median bleaching level among Agariciidae colonies was 10 percent, and the maximum was 58 percent. The only other *Pachyseris* reported, *P. speciosa*, bleached at a rate of 38 percent (Done *et al.*, 2003b). All colonies of *P. rugosa* were partly bleached at Laem Set at Samui Island in the western Gulf of Thailand in 1998, and all were completely bleached in 2010. However, after both bleaching events, all colonies recovered and were healthy (Sutthacheep *et al.*, 2013). In Palau in 2000, *P. rugosa* had variable but generally high bleaching levels and high mortality: 48 percent of all colonies of all species were bleached, and bleaching of different genera and species ranged from none to very high, and mortality from zero to near 100 percent (Bruno *et al.*, 2001). Based on species specific and genus information presented above, *P. rugosa* is predicted to have a moderate to high level of susceptibility to bleaching. With regard to disease, Page and Willis (2007) reported that skeletal eroding band has been found in *P. rugosa* on the GBR, where it is the most prevalent disease on corals. However, the prevalence on *P. rugosa* was too low to record in transects. Darling *et al.* (2012) performed a biological trait-based analysis to categorize the relative tolerance of coral species to environmental stress. *Pachyseris rugosa* was classified as a "generalist" species, defined as species that can do well in habitats where competition is limited by low levels of stress. There are no other

reports of the effects of any other threats on *P. rugosa*. Based on genus-level and species-specific information describe above, *P. rugosa* is likely to have high susceptibility to ocean warming and some susceptibility to disease, ocean acidification, trophic effects of fishing, nutrients, sedimentation, sea level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibility of *P. rugosa* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanism or conservation efforts for *P. rugosa*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *P. rugosa* occurs in 57 Indo-Pacific ecoregions that encompass 36 countries' EEZs. The 36 countries are Australia, Brunei, China, Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (including Andaman and Nicobar Islands), Indonesia, Israel, Japan, Jordan, Madagascar, Malaysia, Maldives, Mauritius, Myanmar, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Sri Lanka, Sudan, Taiwan, Thailand, Timor-Leste, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (American Samoa, PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *P. rugosa*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (28 percent with 6 percent limited in scope), coral collection (61 percent with 31 percent limited in scope), pollution control (44 percent with 8 percent limited in scope), fishing regulations on reefs (92 percent with 19 percent limited in scope), managing areas for protection and conservation (97 percent with 8 percent limited in scope). The most common regulatory mechanisms in place for *P. rugosa* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 31 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *P. rugosa*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *P. rugosa* are that it has had high (but variable) observed bleaching in response to warming events, has been observed to be susceptible to multiple types of disease, and has been inferred to be susceptible to poor water quality. Substantial collection from the aquarium trade could lead to local extirpation in some areas. It listed factors that reduce potential extinction risk including that *P. rugosa* has a widespread distribution from the central Pacific to Africa, and it can have a high local abundance.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *P. rugosa*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean, and some in the Red Sea. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from five to at least 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than

surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore, there will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. rugosa* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *P. rugosa* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *P. rugosa*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to likely become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Pachyseris rugosa*'s distribution from the Red Sea across the Indian Ocean and most of the Pacific Ocean includes tens of thousands of islands and reefs spread over a vast area. While

some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Pachyseris rugosa* is described as common throughout its vast geographic range and its total population size is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *P. rugosa* is not warranted for listing at this time under any of the listing factors.

#### Genus *Pavona*

##### Genus Introduction

The family Agaricidae includes six genera, *Agaricia* (Caribbean only), *Leptoseris*, *Pavona*, *Pachyseris*, *Gardineroseris*, and *Coeloseris*. Veron

(Veron, 2000) recognizes 14 species in the genus *Pavona*. Colonies of *Pavona* species have plates, branches, or are massive. The SRR and SIR provided no genus-level introductory information on *Pavona*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Pavona*. One study reports *Pavona* had mixed bleaching susceptibility on the GBR. Other studies reported that both massive and encrusting *Pavona* have been highly susceptible to bleaching in the eastern Pacific. Calcification in one *Pavona* species slowed in reduced aragonite saturation state. Two massive *Pavona* in the eastern Pacific showed little calcification reduction over 30 years in response to acidification. The presence of several species of *Pavona* in low aragonite saturation states in the Eastern Pacific suggests some tolerance to acidification. There are a medium number of acute white diseases found in *Pavona* by surveys in the Pacific. Members of the genus *Pavona* are susceptible to predation by crown-of-thorns seastar (*Acanthaster planci*), but susceptibility is variable among species in the eastern Pacific. The genus *Pavona* is generally regarded as moderately tolerant to sediment stress. More than 1,000 pieces of *Pavona* are traded per year.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Pavona*. We gathered supplemental information that provided the following. With regard to thermal stress, Brown and Suharsono (1990) reported that less than half of the *Pavona* on the reef flats of two islands in the Thousand Islands of Indonesia died in the 1983 El Niño mass bleaching. In the mass bleaching event in 1998 in the Ryukyu Islands of Japan, *Pavona* was highly susceptible to bleaching, and mortality was 100 percent, higher than any other of the six genera included in the study (Kayanne *et al.*, 2002). In contrast, during the same 1998 bleaching event in Kenya, mortality of *Pavona* colonies was zero, and *Pavona* was one of five genera out of the 18 genera in the study that had no mortality (McClanahan *et al.*, 2004). *Pavona*'s bleaching index was the second lowest of the 18 genera (McClanahan *et al.*, 2004). In a bleaching event on Palau in 2000, three species of *Pavona* had high levels of bleaching and high mortality. Forty-eight percent of all colonies of all species were bleached, and both bleaching and mortality of different

genera and species ranged from zero to near 100 percent (Bruno *et al.*, 2001). In a bleaching event on the GBR in 2002, between seven percent and 57 percent of six species of *Pavona* were affected (Done *et al.*, 2003b). In a bleaching event on Mauritius in 2004, *Pavona* had the fourth lowest bleaching of the 32 genera recorded (McClanahan *et al.*, 2005a). In a bleaching event on Howland and Baker Islands in 2010, between 32 and 37 percent of *Pavona* colonies bleached (Vargas-Angel *et al.*, 2011). During the same 2010 bleaching event in Thailand, between 47 and 67 percent of *Pavona* colonies bleached (Sutthacheep *et al.*, 2013).

In a broad study of 45 genera in the western Indian Ocean in 1998 to 2005, *Pavona* ranked 31st in bleaching susceptibility (McClanahan *et al.*, 2007a). *Pavona* had a low prevalence of disease in Guam, with 0.5% of colonies with disease, tied for sixth highest prevalence out of 12 genera, with the highest genus having 6.7 percent (Myers and Raymundo, 2009). There is no other supplemental information on the susceptibilities or vulnerabilities of *Pavona* to other threats.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Pavona* species to ocean warming, disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. There was a wide range of reported susceptibility of *Pavona* colonies to ocean warming and acidification. One study reported a moderate disease prevalence in *Pavona* and another reported a low prevalence. Thus, we conclude that an unstudied *Pavona* species is likely to have some susceptibility to ocean warming, disease, and acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa,

as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Pavona* species is likely to be susceptible to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. The SRR reported that one study showed *Pavona decussata* had an intermediate level of susceptibility to sedimentation. Thus, we conclude that an unstudied *Pavona* species is likely to have some susceptibility to sedimentation. Although there is no genus-level or species-specific information on the susceptibilities of *Pavona* species to nutrients, the SRR rated it as “low-medium” importance to corals. Thus, we conclude that an unstudied *Pavona* species is likely to have some susceptibility to nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Pavona* species is likely to have some susceptibility to sea-level rise. The SRR reported that *Pavona* was susceptible to starfish predation (but the level varied by species) and that the genus is traded in a moderate amount. Thus, we conclude that an unstudied *Pavona* species has some susceptibility to predation and to collection and trade.

In conclusion, an unstudied *Pavona* species is likely to have some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, nutrients, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### *Pavona diffluens*

##### Introduction

The SRR and SIR provided the following information on *P. diffluens*’ morphology and taxonomy. Morphology was described as submassive, and the taxonomy was described as having no taxonomic issues, but it is similar to *Pavona gigantea* and *Pavona explanulata*.

The public comments and information we gathered did not provide any new or supplemental information on morphology. There is high taxonomic uncertainty about colonies that appear similar to *P. diffluens* in the Pacific, but low taxonomic uncertainty about *P. diffluens* in the Red Sea and Indian Ocean. Both colonies in the Red Sea/ Indian Ocean, and in the Pacific, are easily distinguished from other *Pavona*. Veron (2014) states that, “We believe

that Pacific *P. diffluens* is likely to be a similar but different species from western Indian Ocean *P. diffluens*.” We treat *P. diffluens* as the colonies in the Red Sea and Indian Ocean only, as this is the best currently available scientific information. Veron (2000; 2014) considers the species valid, and we consider it is sufficiently distinctive to be identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *P. diffluens*’ distribution, habitat, and depth range. *Pavona diffluens* occurs from the Red Sea to the Arabian Gulf, and records show this species from the Marianas Islands and American Samoa, but the records from the Marianas Islands were unlikely. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons, in depths ranging from five to at least 20 m.

The public comments and information we gathered provided supplemental information on the distribution of *P. diffluens*. One public comment stated that the occurrence of *P. diffluens* in the Marianas indicates that this species has a broader range than has been recognized by the authors. We gathered supplemental information, including additional reports of *P. diffluens* from American Samoa (Fenner, 2014b; Kenyon *et al.*, 2010), but the taxonomic question for them remains. Veron (2014) reports that this species is confirmed in five of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional three, all of which are in the western Indian Ocean. The public comments and information we gathered provided nothing new or supplemental on *P. diffluens*’ habitat and depth range.

##### Demographic Information

The SRR and SIR provided the following information on *P. diffluens*’ abundance. *Pavona diffluens* has been reported as uncommon.

The public comments did not provide any new or supplemental information on *P. diffluens*’ abundance, but we gathered supplemental information that provided the following: Veron (Fenner, 2014b; Veron, 2014) reported that *P. diffluens* occupied 0.47% of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.43 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species’ abundance is characterized as

“rare,” and overall abundance is described as “uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *P. diffluens*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 20 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, these changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. diffluens* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *P. diffluens*’ life history. The reproductive characteristics of *P. diffluens* have not been determined, but six other species in the genus are known to be gonochoric broadcast spawners. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *P. diffluens*’ threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Pavona* of ocean warming, disease, acidification, sedimentation, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. diffluens*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule as follows: High vulnerability to ocean warming, moderate vulnerabilities to disease, ocean acidification, and trophic effects

of fishing, low vulnerabilities to sedimentation, sea-level rise, predation, and collection and trade, and unknown vulnerability to nutrients.

Public comments did not provide any new or supplemental information on *P. diffluens*’ threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species’ threat susceptibilities. *P. diffluens* has not been rated as moderately or highly susceptible to bleaching or disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). There is no species-specific information for the exposure or susceptibility of *P. diffluens* to any threat. Based on genus-level and species information described above, *P. diffluens* likely has some susceptibilities to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *P. diffluens* to the threats.

#### Regulatory Mechanisms

In the proposed rule we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *P. diffluens*. Criticisms of our approach received during public comment led us to the following analysis to attempt to analyze regulatory mechanisms on a species basis. Records confirm that *Pavona diffluens* occurs in five Indo-Pacific ecoregions that encompass 14 countries’ EEZs. The 14 countries are Djibouti, Egypt, Eritrea, France (French Pacific Island Territories), Iran, Israel, Jordan, Madagascar, Oman, Pakistan, Saudi Arabia, Sudan, United Arab Emirates, and Yemen. The regulatory mechanisms relevant to *P. diffluens*, described first as the percentage of the above countries that utilize them to any degree, and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (21 percent with 7 percent limited in scope), coral collection (43 percent with 7 percent limited in scope), pollution control (64 percent with 7 percent limited in scope), fishing regulations on reefs (71 percent with 21 percent limited in scope), and managing areas for protection and conservation (79 percent with 21 percent limited in scope). The most common regulatory mechanisms in place for *P. diffluens* are reef fishing regulations and area management for protection and conservation. Pollution control laws are also common for the species. Coral

collection and general coral protection laws are less common regulatory mechanisms for the management of *P. diffluens*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species’ vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that *P. diffluens*’ fairly moderate-to-low tolerance to thermal stress and the species’ narrow distribution range increase the potential extinction risk. It listed factors that reduce potential extinction risk for *P. diffluens* including its moderate tolerance of sediment stress and its low susceptibility of the genus to disease and predation.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species’ vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species’ spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species’ susceptibility to threats.

The following characteristics of *P. diffluens*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is limited only to parts of the western Indian Ocean along coastal East Africa, the Red Sea, and the Gulf of Oman. This range exacerbates vulnerability to extinction over the foreseeable future because of its size and localized human impacts for coral reefs over the 21st century. In addition, parts of the Red Sea are projected to experience severe impacts from climate change more rapidly than other parts of the Indo-Pacific region. Its depth range of five to 25 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the

species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. However, its qualitative abundance is described as rare, which can exacerbate its vulnerability given its restricted range.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. diffluens* was proposed for listing as threatened because of: Moderate vulnerability to ocean warming (ESA Factor E), disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, the listing determination for *P. diffluens* remained threatened. Based on the best available information provided above on *P. diffluens*' spatial structure, demography, threat susceptibilities, and management, it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Pavona diffluens* is susceptible to ocean warming (E), disease (C), ocean acidification (E), trophic effects of fishing (A), nutrients (A, E), and predation (C). In addition, the species has inadequate regulatory mechanisms for global threats (D);

(2) *Pavona diffluens*' distribution is mostly constrained to a small part of the Indian Ocean where projections of local threats (e.g., land-based sources of pollution) and general effects of climate change are both frequent and severe over the foreseeable future. The Red Sea in particular is projected to experience frequent warming events sooner than most other parts of the Indo-Pacific region. A range constrained to a

particular geographic area this size, predicted to experience increasing threat impacts, indicates that a high proportion of the population of this species is likely to be exposed to threats that occur throughout this range over the foreseeable future; and

(3) *Pavona diffluens*' qualitative abundance is rare, which means it does not possess as much buffering capacity in the form of variability in response between individuals or absolute abundance that would be afforded to a more abundant or common species. Combined with the limited range of this species, this level of abundance leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *P. diffluens*' spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *P. diffluens*' distribution is constrained only to parts the western Indian Ocean along coastal East Africa, the Red Sea, and the Gulf of Oman, the species' range still includes heterogeneous habitat across its range, including at least upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons. Thus, the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented or geographically constrained that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) While *P. diffluens*' qualitative abundance is rare, its absolute abundance is at least millions of colonies, which allows for some variation in the responses of individuals to threats. There is no evidence of

depensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its abundance indicates it is currently able to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events.

The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *P. diffluens*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., GHG emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### *Genus Pectinia*

##### Genus Introduction

The family Pectiniidae includes five genera, *Pectinia*, *Echinomorpha*, *Echinophyllia*, *Oxypora* and *Mycedium*. Veron (2000) recognizes nine species of *Pectinia*. Colonies are laminar to branching, and may have high walls separating wide valleys. The SRR and SIR provided no genus-level introductory information on *Pectinia*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Pectinia*. A case study from the Waikiki Aquarium reported tolerance of *Pectinia alcornis* to low pH. With regards to disease, the SRR referred to a study that reported crustacean parasites in *Pectinia lactuca* in American Samoa. However, taxonomists have not recorded any *Pectinia* species there so far (D. Fenner, personal comm.). Another study referred to in the SRR reported *Pectinia* was not infected by ciliate skeletal eroding band on the GBR. The SRR referred to two studies that reported that *Pectinia* is tolerant of sediment, one study that indicated it was tolerant of high nutrients, and one study that reported it decreased along a gradient of reduced water quality. The SRR reported that Pectiniidae species are

highly susceptible to crown-of-thorns seastar. The SRR reported that the genus *Pectinia* is heavily exported—several thousand specimens are exported annually.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Pectinia*. We gathered supplemental information that provided the following. With regard to thermal stress, during a bleaching event on the GBR in 2002, between five and 11 percent of three species of *Pectinia* were affected (Done *et al.*, 2003a). In Palau in 2000, *Pectinia lactuca* and *Pectinia peonia* both had high levels of bleaching and high mortality. Forty-eight percent of all colonies of all species were bleached, and both bleaching and mortality of different genera and species ranged from zero to near 100 percent (Bruno *et al.*, 2001). Ruiz-Moreno *et al.* (2012) reported that the family Pectinidae had the highest disease prevalence of any family of corals in the Pacific, and third highest of all coral families they studied in the Caribbean and Indo-Pacific. However, the family Pectinidae has five genera, and the study did not report on the genus *Pectinia*. There is no other supplemental information on the susceptibilities of *Pectinia* to threats.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Pectinia* species to ocean warming, disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. *Pectinia* shows a variable level of warming-induced bleaching, thus we conclude that an unstudied *Pectinia* is likely to have some susceptibility to ocean warming. Although there is no other genus-level or species-specific information on the susceptibility of *Pectinia* species to disease, the SRR rated it as “high” importance to corals, thus we conclude that an unstudied *Pectinia* is likely to have some susceptibility to disease. One study reported one species of *Pectinia* had some resistant to acidification, thus with only one study, we conclude that an unstudied *Pectinia* is likely to have some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Pectinia* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. Studies of the effects of sediment and nutrients on *Pectinia* were inconsistent, thus we conclude that an unstudied *Pectinia* species is likely to have some susceptibility to sediment and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Pectinia* species is likely to have some susceptibility to sea-level rise. The SRR reported that Pectinidae species are highly susceptible to crown-of-thorns seastar, thus we conclude that an unstudied *Pectinia* species is likely to have some susceptibility to collection and trade. The SRR rated ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. The SRR reported that *Pectinia* is heavily traded, thus we conclude that an unstudied *Pectinia* species is likely to have some susceptibility to collection and trade.

In conclusion, an unstudied *Pectinia* species is likely to have some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade.

#### *Pectinia alcornis*

##### Introduction

The SRR and SIR provided the following information on *P. alcornis*' morphology and taxonomy. Morphology was described as irregular clusters with thin, flat, grooved plates and tall, upward-projecting spires that can dominate its structure. The taxonomy was described as having no taxonomic issues but being similar in appearance to *Pectinia paeonia*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *P. alcornis*, but a moderate level of species identification uncertainty exists. Veron (2014) states that *P. alcornis* is sometimes confused with other *Pectinia* species and Veron (2000; 2014) considers the species valid, thus we conclude it can be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *P. alcornis*' distribution, habitat, and depth range. The SRR and SIR described *P. alcornis*' distribution as broadly distributed from the northern Indian Ocean to Fiji. It inhabits turbid water and other low-light environments in most coral reef habitats, including at least upper reef slopes, mid-slopes, lagoons, and caves, at depths of five to 25 m.

Public comments did not provide any new or supplemental information on *P. alcornis*' distribution. We gathered supplemental information including, Veron (2014), which reports that this species is confirmed in 39 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 16.

##### Demographic Information

The SRR and SIR reported *P. alcornis*' abundance as usually uncommon.

Public comments did not provide any new or supplemental information on *P. alcornis*' abundance. We gathered supplemental information including Veron (2014), which reports that *P. alcornis* occupied 16.6 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.6 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “common,” and overall abundance was described as “usually uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from

total live coral cover trends and habitat types. For *P. alvicornis*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 38 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. alvicornis* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR reported that *P. alvicornis* is a hermaphroditic broadcast spawner. The public comments and information we gathered provided no new or supplemental biological information.

#### Susceptibility to Threats

To describe *P. alvicornis*’ threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Pectinia* of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR also provided the following species-specific information on *P. alvicornis*’ threats. *Pectinia alvicornis* harbors Clade C zooxanthellae in Okinawa and the South China Sea, but contained Clade D zooxanthellae in Palau after the 2001 mass bleaching event. It is one of many species that has been raised in the Waikiki Aquarium, which is characterized by high-nutrient, low-pH waters. Although it is generally a sediment-tolerant genus, *P. alvicornis* decreased along a deteriorating water

quality gradient on the Great Barrier Reef. *Pectinia alvicornis* exports were reported at the species level only for 2000–2003, with a total of 133 specimens reported. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. alvicornis*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *P. alvicornis*’ vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and predation, and low vulnerability to sedimentation, nutrients, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *P. alvicornis*’ threats susceptibilities. We gathered supplemental species-specific and genus-level information on this species’ threat susceptibilities. *Pectinia alvicornis* has been rated as moderately or highly susceptible to bleaching but not to disease, however this rating is not based on species-specific data (Carpenter *et al.* 2008). With regard to thermal stress, eight percent of *P. alvicornis* was affected by bleaching on the GBR in 2002. The other two *Pectinia* species included in the study were affected by bleaching at rates of three percent and 12 percent, and the range for all members of family Pectiniidae was zero to 17 percent (Done *et al.*, 2003a). There is no other supplemental information on the effects of threats on this species. Based on genus-level and species-specific information described above, *P. alvicornis* likely has some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of this species’ threat susceptibilities.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *P. alvicornis*. Public comments were critical of that approach and we therefore attempt to analyze regulatory mechanisms on a species basis in this final rule. Records confirm that *Pectinia alvicornis* occurs in 39 Indo-Pacific ecoregions that encompass 21 countries’ EEZs. The 21 countries are Australia, Brunei, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Japan, Malaysia, Myanmar, Palau, Papua New Guinea, Philippines, Solomon Islands,

Sri Lanka, Taiwan, Thailand, Timor-Leste, Vanuatu, and Vietnam. The regulatory mechanisms relevant to *P. alvicornis*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (33 percent with 10 percent limited in scope), coral collection (52 percent with 29 percent limited in scope), pollution control (38 percent with 14 percent limited in scope), fishing regulations on reefs (100 percent with 14 percent limited in scope), and managing areas for protection and conservation (95 percent with none limited in scope). The most common regulatory mechanisms in place for *P. alvicornis* are reef fishing regulations and area management for protection and conservation. Coral collection laws are also somewhat utilized for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection and pollution control laws are less common regulatory mechanisms for the management of *P. alvicornis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species’ vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that high bleaching rate is the primary threat of extinction for *Pectinia*, although *P. alvicornis* may be relatively resistant in some areas. Factors that increase potential extinction risk for *P. alvicornis* include susceptibility to bleaching, predation, and harvesting. It listed factors that reduce potential extinction risk including that *P. alvicornis* occupies a variety of habitat types and is broadly distributed both latitudinally and longitudinally in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species’ vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species’ spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed

to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *P. alvicornis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is from the northern Indian Ocean to Fiji. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is five to 25 m. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its inhabits turbid water and other low-light environments in most coral reef habitats, including at least upper reef slopes, mid-slopes, lagoons, and caves. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Turbidity in particular can moderate exposure to high irradiance by blocking light and resulting heat from the water column. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. alvicornis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution

(based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *P. alvicornis* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *P. alvicornis*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to likely become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Pectinia alvicornis*' distribution from the northern Indian Ocean through the western Pacific Ocean to Fiji includes tens of thousands of islands and reefs spread over a vast area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Pectinia alvicornis*' total population size is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) *Pectinia alvicornis* extends down to 25 meters depth, providing some buffering capacity against threat-induced mortality events that may be more severe in shallow habitats;

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *P. alvicornis* is not warranted for listing at this time under any of the listing factors.

#### Genus *Acanthastrea*

##### Genus Introduction

The family Mussidae has 13 genera, eight of which are restricted to the Indo-Pacific, including *Acanthastrea*. The genus *Acanthastrea* contains 12 known species. Most *Acanthastrea* are encrusting, but one is massive. The SRR and SIR provided no genus-level introductory information on *Acanthastrea*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Acanthastrea*. The genus *Acanthastrea* has been reported to be highly susceptible to bleaching in Australia and in the western Indian Ocean. The genus sustained moderate bleaching in Palau in 1994 and several *Acanthastrea* species were relatively unaffected during the 2002 event on the GBR (Done *et al.*, 2003b). Although no exports of *Acanthastrea* were reported from 2000–2009, 1,000 *Acanthastrea* pieces were exported from Indonesia in 2010.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Acanthastrea*. We gathered supplemental information which provided the following details. All *Acanthastrea* in protected areas in Kenya were killed by mass bleaching in 1998 (McClanahan *et al.*, 2001). Out of

four *Acanthastrea* species on the GBR, three species were not affected by the 2002 GBR bleaching event, while 22 percent of one species was affected (Done *et al.*, 2003b). At Mauritius in a bleaching event in 2004, *Acanthastrea* had a bleaching index of nine, the 22nd highest of the 32 genera recorded, which was 14 percent of the index of the genus with the highest index (McClanahan *et al.*, 2005a). In the western Indian Ocean in 1998–2005, *Acanthastrea* had a bleaching index of 14.4 for eight countries, which was 24th highest of the 45 genera recorded, and 35 percent of the highest value (McClanahan *et al.*, 2007a).

With regard to land-based sources of pollution, Stafford-Smith (1993) reported that 14 of 20 *Acanthastrea echinata* samples cleared over 98 percent of sediment within 48 hours, the 12th best score. This score was 70 percent of the highest scoring species. There is no other supplemental information on the effects of threats on the genus *Acanthastrea*.

#### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Acanthastrea* species to ocean warming, disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. The above information on *Acanthastrea* shows a wide range of susceptibility to ocean warming, thus we conclude that an unstudied *Acanthastrea* species is likely to have some susceptibility to ocean warming. Although there is no genus-level or species-specific information on the susceptibilities of *Acanthastrea* species to disease and ocean acidification, the SRR rated it as “medium-high” importance to corals. Thus, we conclude that an unstudied *Acanthastrea* species is likely to have some susceptibility to disease and ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a

competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Acanthastrea* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. One study found an *Acanthastrea* species to have moderate sediment-clearing ability. Thus we conclude that an unstudied *Acanthastrea* species is likely to have some susceptibility to sedimentation. Although there is no genus-level or species-specific information on the susceptibilities of *Acanthastrea* species to nutrients, the SRR rated it as “low-medium” importance to corals. Thus, we conclude that an unstudied *Acanthastrea* species has some susceptibility to nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Acanthastrea* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. Although there is no genus-level or species-specific information on the susceptibilities of *Acanthastrea* species to predation, there is no information suggesting they are not susceptible to this threat. Thus, we conclude that an unstudied *Acanthastrea* species has some susceptibility to predation. Because the available information suggests that *Acanthastrea* species are lightly collected and traded, an unstudied *Acanthastrea* species is likely to have low susceptibility to collection and trade.

In conclusion, an unstudied *Acanthastrea* species is likely to have some susceptibility to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, and predation, and is likely to have low susceptibility to collection and trade.

#### *Acanthastrea brevis*

##### Introduction

The SRR and SIR provided the following information on *A. brevis*’ morphology and taxonomy. Morphology was described as mostly submassive, attached and colonial, and the taxonomy was described as having no

taxonomic issues but being similar in appearance to *Acanthastrea echinata*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. brevis*, but a moderate to high level of species identification uncertainty. Veron (2014) states that it is “readily confused with *Acanthastrea echinata*,” but Veron (2000; 2014) considers the species valid, thus we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. brevis*’ distribution, habitat, and depth range. *Acanthastrea brevis* is distributed from the Red Sea and western Indian Ocean to American Samoa in the central Pacific. Its habitat includes all coral reef habitats, in a depth range of one to 20 m.

Public comments provided the following information on distribution for *A. brevis*. One public comment stated that *A. brevis* likely occurs in the Marianas and will be included in an upcoming book. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 29 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 17. *Acanthastrea brevis* is found in the Northern Marianas and American Samoa as well (D. Fenner, personal comm.) and the Marianas are one of the predicted areas for *A. brevis* in the Veron (2014) information. Public comments and information we gathered did not provide any more information on the habitat and depth range of this species.

##### Demographic Information

The SRR and SIR reported *A. brevis*’ abundance as uncommon but conspicuous.

Public comments did not provide any new or supplemental information on *A. brevis*’ abundance. We gathered supplemental information, including Veron (2014), which reports that *A. brevis* occupied 6.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.49 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species’ abundance was characterized as “uncommon,” and overall abundance was also described as “uncommon.”

Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. brevis*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. brevis* occurs in many areas affected by these broad changes, and likely has some susceptibility to both local and global threats, we conclude it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. brevis*’ life history. Although specific larval descriptions have not been published for this species, the larvae of three other *Acanthastrea* species studied do not contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *A. brevis*’ threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acanthastrea* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR

did not provide any other species-specific information on the effects of these threats on *A. brevis*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. brevis*’ vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, and trophic effects of fishing, and low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown vulnerability to nutrients.

Public comments did not provide any new or supplemental information on *A. brevis*’ threats susceptibilities. We gathered supplemental species-specific and genus-level information on this species’ threat susceptibilities. *Acanthastrea brevis* was not rated as moderately or highly susceptible to bleaching or coral disease by Carpenter *et al.* (2008), but they did not use species-specific data for their ratings. Based on genus-level and species information described above, *A. brevis* likely has some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, nutrients, sedimentation, sea-level rise, and predation, and low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. brevis*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *Acanthastrea brevis* occurs in 29 Indo-Pacific ecoregions that encompass 31 countries’ EEZs. The 31 countries are Australia, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Jordan, Kiribati, Madagascar, Malaysia, Mauritius, New Zealand (Tokelau), Niue, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan, Tonga, Tuvalu, United Kingdom (British Indian Ocean Territory), United States (American Samoa), Vietnam, and Yemen. The regulatory mechanisms relevant to *A. brevis*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (29 percent with 6 percent limited in scope), coral collection (65 percent with 26 percent

limited in scope), pollution control (55 percent with 10 percent limited in scope), fishing regulations on reefs (90 percent with 19 percent limited in scope), and managing areas for protection and conservation (97 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. brevis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are somewhat common for the species, but 26 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. brevis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species’ vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that high susceptibility to bleaching is the primary factor that increases potential extinction risk for *A. brevis*. It listed factors that reduce potential extinction risk for *A. brevis* including the fact that it occupies a variety of habitat types and is broadly distributed, both latitudinally and longitudinally, in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species’ vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species’ spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species’ susceptibility to threats.

The following characteristics of *A. brevis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat sub-section, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is from the Red Sea and western Indian Ocean to American Samoa in the central Pacific. Its geographic distribution moderates vulnerability to extinction because some

areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from one to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes all coral reef habitats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. brevis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. brevis* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. brevis*' spatial structure, demography, threat susceptibilities, and management,

none of the five ESA listing factors, alone or in combination, are causing this species to likely become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Acanthastrea brevis*' distribution from the western Indian Ocean to the central Pacific across is spread over a vast area, approximately half of the Indo-Pacific region. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Acanthastrea brevis*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A.*

*brevis* is not warranted for listing at this time under any of the listing factors.

#### *Acanthastrea hemprichii*

##### Introduction

The SRR and SIR provided the following information on *A. hemprichii*'s morphology and taxonomy. Morphology was described as encrusting to massive and frequently over one meter across, and the taxonomy was described as having no taxonomic issues but being similar in appearance to *Acanthastrea echinata*, *Acanthastrea bowerbanki*, and *Acanthastrea hillae*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. hemprichii* and a low to moderate level of species identification uncertainty. Veron (2014) states that *A. hemprichii* is usually distinctive and Veron (2000; 2014) considers the species valid, thus we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *A. hemprichii*'s distribution, habitat, and depth range. *Acanthastrea hemprichii*'s distribution extends from the Red Sea and east Africa to the central Indo-Pacific and central Pacific, it occupies most reef habitats, and its depth range is from two to 20 m depth.

Public comments did not provide any new or supplemental information on *A. hemprichii*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 47 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 23.

##### Demographic Information

The SRR and SIR reported *A. hemprichii*'s abundance as uncommon.

Public comments did not provide any new or supplemental information on *A. hemprichii*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *A. hemprichii* occupied 11.4 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.47 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as

“common,” and overall abundance was described as “uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *Acanthastrea hemprichii*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. hemprichii* occurs in many areas affected by these broad changes, and likely has some susceptibility to local and global threats, we conclude it has likely declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. hemprichii*'s life history. Although specific larval descriptions have not been published for this species, the larvae of three other *Acanthastrea* species studied do not contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *A. hemprichii*'s threat susceptibilities, the SRR and SIR provided genus-level information for the

effects on *Acanthastrea* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *A. hemprichii*'s threats. *Acanthastrea hemprichii* was relatively unaffected during the 2002 bleaching event on the Great Barrier Reef. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. hemprichii*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. hemprichii*'s vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and predation, low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown susceptibility for nutrients.

Public comments did not provide any new or supplemental information on *A. hemprichii*'s threats. We gathered supplemental species-specific and genus-level information on this species' threat susceptibilities. *Acanthastrea hemprichii* was not rated as moderately or highly susceptible to bleaching or disease by Carpenter *et al.* (2008), but they did not have species-specific data. Done *et al.* (2003b) reported no bleaching in *A. hemprichii* on the GBR in 2002. Eight of 14 species of Mussidae bleached with six to 26% of colonies bleached, and for species in other families, as much as 80% of colonies bleached. Based on genus-level and species-specific information described above, *A. hemprichii* likely has some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, nutrients, sedimentation, sea level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibility of *A. hemprichii* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. hemprichii*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *Acanthastrea hemprichii* occurs in 47 Indo-Pacific ecoregions that encompass 30 countries' EEZs. The 30 countries are Australia, China, Djibouti, Egypt, Eritrea, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (Andaman and Nicobar Islands), Indonesia, Israel,

Japan, Jordan, Kenya, Madagascar, Malaysia, Marshall Islands, Myanmar, Papua New Guinea, Philippines, Saudi Arabia, Seychelles, Solomon Islands, Somalia, Sudan, Taiwan, Tanzania, Thailand, Vietnam, and Yemen. The regulatory mechanisms relevant to *A. hemprichii*, first described as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (20 percent with three percent limited in scope), coral collection (47 percent with 20 percent limited in scope), pollution control (43 percent with 10 percent limited in scope), fishing regulations on reefs (87 percent with 17 percent limited in scope), and managing areas for protection and conservation (90 percent with 10 percent limited in scope). The most common regulatory mechanisms in place for *A. hemprichii* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are somewhat common for the species, but 20 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. hemprichii*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that high susceptibility to bleaching is the primary factor that increases potential extinction risk for *A. hemprichii*. It listed factors that reduce potential extinction risk for *A. hemprichii* are includes the fact that it occupies a variety of habitat types and is broadly distributed, both latitudinally and longitudinally, in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed

to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. hemprichii*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Red sea and western Indian Ocean and many in the central Indo-Pacific and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from two to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes most reef habitats. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. hemprichii* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E);

and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. hemprichii* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. hemprichii*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Acanthastrea hemprichii*'s distribution includes the Red Sea and east coast of Africa, plus many of the coral reef ecoregions in the central Indo-Pacific and central Pacific Ocean includes and is spread over a vast area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Acanthastrea hemprichii*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity

to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. hemprichii* is not warranted for listing at this time under any of the listing factors.

#### *Acanthastrea ishigakiensis*

##### Introduction

The SRR and SIR provided the following information on *A. ishigakiensis*' morphology and taxonomy. Morphology was described as massive and usually hemispherical and often more than 0.5 meters across, and taxonomy was described as having no taxonomic issues but being similar in appearance to *Acanthastrea hillae* and *Symphyllia erythraea*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. ishigakiensis*, but that there is a moderate level of species identification uncertainty for this species. Veron (2014) states that *A. ishigakiensis* is readily confused with *A. hillae*, but Veron (2000; 2014) also considers the species valid, thus we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *Acanthastrea ishigakiensis*' distribution, habitat, and depth range. *Acanthastrea ishigakiensis*' distribution extends from the Red Sea and east coast of Africa to the central Pacific, but excludes Australia. Its habitat includes upper reef slopes, lagoons and other areas protected from wave action, in depths from one to 15 m depth.

Public comments provided the following information on *A. ishigakiensis*' distribution. One public

comment stated that R.H. Randall recalls seeing this species in Guam at 60 m deep. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 25 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 19.

#### Demographic Information

The SRR and SIR reported *A. ishigakiensis*' abundance as uncommon but conspicuous.

Public comments did not provide any new or supplemental information on *A. ishigakiensis*' abundance. We gathered supplemental information, including Veron (2014), which reports that *A. ishigakiensis* occupied 2.9 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.3 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was described as "uncommon but conspicuous." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. ishigakiensis*, the overall decline in abundance ("Percent Population Reduction") was estimated at 34 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. ishigakiensis* occurs in many areas affected by these broad changes, and likely has some susceptibility to local and global threats, we conclude it has

likely declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the lack of species specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. ishigakiensis*' life history. Although specific larval descriptions have not been published for this species, the larvae of three other *Acanthastrea* species studied do not contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis. The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *A. ishigakiensis*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acanthastrea* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. ishigakiensis*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. ishigakiensis*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and predation, low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown susceptibility to nutrients.

Public comments did not provide any new or supplemental information on *A. ishigakiensis*' threats susceptibilities. We gathered supplemental species-specific and genus-level information on this species' threat susceptibilities. *Acanthastrea ishigakiensis* was not rated as moderately or highly susceptible to bleaching or disease by Carpenter *et al.* (2008), but they did not have species-specific data. No species-specific information is available for the susceptibility of *A. ishigakiensis* to any threat. Based on genus-level information described above, *A. ishigakiensis* likely has some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, nutrients, sedimentation, sea level rise, predation, and low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific

information on the regulatory mechanisms or conservation efforts for *A. ishigakiensis*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm *A. ishigakiensis* occurs in 24 Indo-Pacific ecoregions that encompass 25 countries' EEZs. The 25 countries are Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Israel, Japan, Jordan, Kenya, Madagascar, Malaysia, Mauritius, Mozambique, Papua New Guinea, Philippines, Saudi Arabia, Seychelles, Solomon Islands, Sudan, Tanzania, United States (CNMI, Guam), Vanuatu, Vietnam, and Yemen. Regulatory mechanisms relevant to *A. ishigakiensis*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (21 percent with eight percent limited in scope), coral collection (63 percent with 25 percent limited in scope), pollution control (50 percent with 13 percent limited in scope), fishing regulations on reefs (88 percent with 21 percent limited in scope), and managing areas for protection and conservation (100 percent with eight percent limited in scope). The most common regulatory mechanisms in place for *A. ishigakiensis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are somewhat common the species, but 25 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. ishigakiensis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that high susceptibility to bleaching is the primary factor that increases potential extinction risk for *A. ishigakiensis*. It listed factors that reduce potential extinction risk including the fact that *A. ishigakiensis* is broadly distributed, both latitudinally and longitudinally, in the Indo-Pacific.

Subsequent to the proposed rule, we received and gathered supplemental

species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. ishigakiensis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Red Sea and western Indian Ocean and many in the western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from one to 15 meters, and there is one anecdotal record from Guam of this species observed at 60 meters depth. On one hand, its depth range may moderate vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. On the other hand, its depth range may exacerbate vulnerability to extinction over the foreseeable future if the species occurs predominantly in the shallower portion of its depth range, since those areas will have higher irradiance and thus be more severely affected by warming-induced bleaching. Its habitat includes upper reef slopes, lagoons, and other areas protected from wave action. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its

absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. ishigakiensis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on wide geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. ishigakiensis* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. ishigakiensis*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Acanthastrea ishigakiensis*' distribution includes the Red Sea and most of the western Indian Ocean along with many of the coral reef ecoregions in the western and central Pacific. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not

identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Acanthastrea ishigakiensis*' absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. ishigakiensis* is not warranted for listing at this time under any of the listing factors.

#### *Acanthastrea regularis*

##### Introduction

The SRR and SIR provided the following information on *A. regularis*' morphology and taxonomy. Morphology was described as massive and with corallites united by fused compound walls, and taxonomy was described as having no taxonomic issues but being similar in appearance to *Montastraea* and *Favia* underwater.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *A. regularis*, and a moderate level of species identification uncertainty for this species. Veron (2014) states that *A.*

*regularis* is readily confused with *Favia* species but Veron (2000; 2014) considers the species valid, thus we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *A. regularis*' distribution, habitat, and depth range. *Acanthastrea regularis*' distribution is restricted, and includes the Coral Triangle and some islands in the west and central Pacific. Its habitat includes most reef habitats, including upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons in depths from two to 20 m.

Public comments provided the following information on distribution of *A. regularis*. One public comment stated that *A. regularis* is likely in the Marianas. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 17 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 16.

#### Demographic Information

The SRR and SIR reported *A. regularis*' abundance as uncommon.

Public comments did not provide any new or supplemental information on *A. regularis*' abundance. We gathered supplemental information, including Veron (2014), which reports that *A. regularis* occupied 5.1 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.21 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *A. regularis*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above

in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *A. regularis* occurs in many areas affected by these broad changes, and likely has some susceptibility to local and global threats, we conclude it has likely declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species-specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *A. regularis*' life history. Although specific larval descriptions have not been published for this species, the larvae of three other *Acanthastrea* species studied do not contain zooxanthellae that can supplement maternal provisioning with energy sources provided by their photosynthesis.

The public comments did not provide new or supplemental information, and we did not find new or supplemental information on the above-described biological information.

#### Susceptibility to Threats

To describe *A. regularis*' threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Acanthastrea* of ocean warming, acidification, disease, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *A. regularis*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *A. regularis*' vulnerabilities as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, and trophic effects of fishing, and predation, low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown vulnerability to nutrients.

Public comments did not provide any new or supplemental information on *A. regularis*' threat susceptibilities. We

gathered supplemental species-specific and genus-level information on this species' threat susceptibilities. *Acanthastrea regularis* was not rated as moderately or highly susceptible to bleaching or disease by Carpenter *et al.* (2008), but they did not have species-specific data. Based on genus-level information presented above, *A. regularis* likely has some susceptibility to ocean warming, disease, ocean acidification, trophic effects of fishing, nutrients, sedimentation, sea-level rise, and predation, and low susceptibility to collection and trade.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *A. regularis*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *A. regularis* occurs in 17 Indo-Pacific ecoregions that encompass eight countries' EEZs. The eight countries are Australia, Federated States of Micronesia, Fiji, Indonesia, Malaysia, Papua New Guinea, Philippines, and Vietnam. The regulatory mechanisms relevant to *A. regularis*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (25 percent with none limited in scope), coral collection (63 percent with 25 percent limited in scope), pollution control (63 percent with 25 percent limited in scope), fishing regulations on reefs (100 percent with 13 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *A. regularis* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 25 percent of those laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *A. regularis*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the

baseline environment and future projections of threats. The SRR stated that high susceptibility to bleaching is the primary factor that increases potential extinction risk for *A. regularis*. This species occupies a variety of habitat types and extends down to 20 meters depth which are factors listed in the SRR that reduce potential extinction risk.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *A. regularis*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. *Acanthastrea regularis* is not highly susceptible to any of the nine most important threats, although it has some susceptibility to each. Its geographic distribution is mostly constrained to parts of the Coral Triangle and western equatorial Pacific Ocean—areas which are projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. For a species that is highly susceptible to climate change related threats, this range would exacerbate vulnerability to extinction but *A. regularis* is not highly susceptible to any local sources of impact either. Its depth range is from two to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes upper reef slopes, mid-slopes, lower reef crests, reef flats, and lagoons. This moderates vulnerability to

extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *A. regularis* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *A. regularis* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *A. regularis*' spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) While *A. regularis*' distribution is mostly constrained to parts of the Coral Triangle and western equatorial Pacific Ocean, its distribution is spread over a large area across the Coral Triangle, the Marianas archipelago, Palau, Micronesia, and Fiji. While some areas within its range are projected to be affected by warming and acidification, *A. regularis* is not highly susceptible to ocean warming, acidification, or any of

the nine most important threats. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Acanthastrea regularis*' absolute abundance is at least millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *A. regularis* is not warranted for listing at this time under any of the listing factors.

#### Genus *Barabattoia*

##### Genus Introduction

The family Favidae includes 24 genera, more than any other family, including *Barabattoia*. *Barabattoia* contains two species, *B. laddi* and *B. amicum*. Colonies are massive or encrusting. The SRR and SIR provided no genus-level introductory information on *Barabattoia*.

### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Barabattoia*. *Barabattoia amicorum* has low-to-moderate bleaching susceptibility with an unknown degree of resultant mortality (Bruno *et al.*, 2001).

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Barabattoia*. We gathered supplemental information that provided the following. With regard to thermal stress, *B. amicorum* experienced low to moderate bleaching in Palau in 2000, but mortality was not reported (Bruno *et al.*, 2001). Forty-eight percent of all colonies of all species were bleached, and bleaching of different genera and species ranged from none to very high, and mortality of different genera and species ranged from none to near 100 percent (Bruno *et al.*, 2001). There is no information on the susceptibilities of *Barabattoia* to any other threats.

### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Barabattoia* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as “high” importance, and ocean acidification as “medium-high” importance, to corals. These were rated as the three most important threats to reef-building corals overall. The one available study on the effects of ocean warming on *Barabattoia* found that *B. amicorum* in Palau experienced low to moderate bleaching (Bruno *et al.*, 2001). Even though there is only one study available, since there are only two species within the genus *Barabattoia*, it is reasonable to make inferences about the susceptibility of *B. laddi* to ocean warming. Although there is no other genus-level or species-specific information on the susceptibilities of *Barabattoia* species to ocean warming, disease, and acidification, the SRR rated them as “high” or “medium-high” importance to corals. Thus, we conclude that an unstudied *Barabattoia* species is likely to have some susceptibility to ocean warming, disease, and acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or

SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Barabattoia* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation, nutrients, and sea-level rise as “low-medium” importance to corals overall. Although there is no genus-level or species-specific information on the susceptibilities of *Barabattoia* species to sedimentation and nutrients, there is no information suggesting they are not susceptible to these threats. Thus we conclude that an unstudied *Barabattoia* species is likely to have some susceptibility to sedimentation and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Barabattoia* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. Because there is no information on the effects of predation and ornamental trade on *Barabattoia*, we conclude that *Barabattoia* has some susceptibility to predation and ornamental trade.

In conclusion, an unstudied *Barabattoia* species is likely to have some susceptibility to ocean warming, disease, acidification, disease, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade.

### *Barabattoia laddi*

#### Introduction

The SRR and SIR provided the following information on *B. laddi*'s morphology and taxonomy: the morphology was described as clusters of tubular corallites, and the taxonomy was described as having no taxonomic issues but being similar in appearance to *B. amicorum* and *Montastraea* sp.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *B. laddi*, and that there is a low to moderate level of

species identification uncertainty for this species, since it is so rare that surveyors get little experience with it. Veron (2014) states that *B. laddi* is distinctive and Veron (2000; 2014) considers the species valid, thus we conclude it is sufficiently distinctive to be identified by experts, and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *B. laddi*'s distribution, habitat, and depth range. *Barabattoia laddi*'s range is somewhat restricted, centered on the Coral Triangle and extending to the central Pacific including perhaps French Polynesia. The SRR and SIR described *B. laddi*'s habitat as recorded only from shallow lagoons, and the depth range as 0 to 10 m. The public comments provided the following details. One public comment stated that *B. laddi* tentatively occurs in Apra Harbor, Guam. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 22 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 15. Surveys in Indonesia record the species at multiple sites with depths greater than 10 m (Bigot and Amir, 2009; Donnelly *et al.*, 2003; Turak and DeVantier, 2003) and surveys in the Maldives record the species at multiple sites with depths up to 20 m (Bigot and Amir, 2009; Donnelly *et al.*, 2003; Turak and DeVantier, 2003). These surveys were done in different habitats, including reef slopes and lagoons. Thus, based on all the available information, *B. laddi*'s habitat includes at least upper reef slopes, mid-slope terraces, and lagoons in depths ranging from zero to 20 m.

#### Demographic Information

The SRR and SIR reported *B. laddi*'s abundance as rare. The public comments did not provide any new or supplemental information on *B. laddi*'s abundance, but we gathered supplemental information, including Veron (2014), which reports that *B. laddi* occupied 5.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.33 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “uncommon,” and overall abundance was described as “rare.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction

above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *B. laddi*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 35 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *B. laddi* occurs in many areas affected by these broad changes, and likely has some susceptibility to local and global threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on the limited species specific information.

#### Other Biological Information

The SRR and SIR provided the following information on *B. laddi*’s life history. The reproductive characteristics of *B. laddi* have not been determined. There is only one other species in the genus, *B. amoricum*, which is a hermaphroditic broadcast spawner that participated in multispecies spawning events at Magnetic Island and Orpheus Island on the Great Barrier Reef. The larvae of *B. amoricum* do not contain zooxanthellae that might supplement maternal provisioning with energy from photosynthesis. The public comments and information we gathered provided no new or supplemental biological information.

#### Susceptibility to Threats

To describe *B. laddi*’s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Barabattoia* of ocean warming, disease, acidification, sedimentation, nutrients, predation, and collection and trade. The SRR and SIR did not provide any other species-

specific information on the effects of these threats on *B. laddi*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *B. laddi*’s vulnerabilities as follows: Moderate vulnerability to ocean warming, disease, acidification, trophic effects of fishing, and nutrients, low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown vulnerability to predation.

Public comments did not provide any new or supplemental information on *B. laddi*’s threats. We gathered the following species-specific supplemental information on this species’ threat susceptibilities. *Barabattoia laddi* has not been rated as moderately or highly susceptible to bleaching or disease, but this rating is not based on species-specific data (2008). No other species-specific information is available for the susceptibility of *B. laddi* to any other threat. Based on the available genus-level information described above, *B. laddi* likely has some susceptibility to ocean warming, disease, acidification, trophic effects of fishing, sedimentation, nutrients, predation, sea-level rise, and collection and trade. The available information does not support more precise ratings of the susceptibility of *B. laddi* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *B. laddi*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm *B. laddi* occurs in 22 Indo-Pacific ecoregions that encompass 15 countries’ EEZs. The 15 countries are Australia, Brunei, China, France (French Pacific Island Territories), Indonesia, Malaysia, Marshall Islands, Palau, Papua New Guinea, Philippines, Solomon Islands, Taiwan, United Kingdom (Pitcairn Islands), United States (PRIAs), and Vietnam. The regulatory mechanisms relevant to *B. laddi*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (33 percent with none limited in scope), coral collection (67 percent with 33 percent limited in scope), pollution control (47 percent with 20 percent limited in scope), fishing regulations on reefs (93 percent with 27 percent limited in scope), and managing areas for

protection and conservation (100 percent with 13 percent limited in scope). The most common regulatory mechanisms in place for *B. laddi* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat common for the species, but 33 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *B. laddi*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species’ vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk are the species’ limited western Pacific distribution, its occurrence in shallow lagoons and its rare abundance.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species’ vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species’ spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species’ susceptibility to threats.

The following characteristics of *B. laddi*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat sub-section, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. *Barabattoia laddi* has not been rated highly susceptible to ocean warming or disease, the two most important threats to corals in this final rule, nor is it highly susceptible to the other threats identified in this rule. Its geographic distribution includes coral reef ecoregions in the western and central Pacific Ocean from Malaysia to the Pitcairn Islands. Its geographic distribution in combination with its low to moderate susceptibility to threats, moderates vulnerability to extinction because it is spread across a large area.

While its range includes the Coral Triangle, it also includes some areas projected to have less than average warming and acidification over the foreseeable future, including the central Pacific so portions of the population in these areas will be less exposed to severe conditions, plus those that are exposed may not show negative responses because of low or moderate susceptibility. Its depth range is from zero to 20 meters. This would exacerbate vulnerability to extinction over the foreseeable future for a species with high susceptibility to the nine most important threats, but *B. laddi* is not highly susceptible. Its habitat includes at least upper reef slopes, mid-slope terraces, and lagoons. Its absolute abundance of at least tens of millions of colonies, combined with low to moderate susceptibility and spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *B. laddi* was proposed for listing as threatened because of: Moderate vulnerability to ocean warming (ESA Factor E), disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on moderate geographic distribution and shallow depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *B. laddi* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *B. laddi*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Barabattoia laddi*'s distribution includes many of the coral reef ecoregions in the western and central Pacific, from Malaysia as far east as the Pitcairn Islands, and is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Barabattoia laddi*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) The best available information suggests that *Barabattoia laddi* is not highly susceptible to any of the nine threats identified in this rule, so even if a proportion of its population overlaps in time and space with a threat event, many colonies may not exhibit a negative response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to depensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future

throughout its range. Therefore, *B. laddi* is not warranted for listing at this time under any of the listing factors.

#### Genus *Caulastrea*

##### Genus Introduction

The family Favidae includes 24 genera, more than any other family, including *Caulastrea*. The genus *Caulastrea* contains five species, including *C. echinulata*. Colonies are branching, and branches may be short or close together. The SRR and SIR provided no genus-level introductory information on *Caulastrea*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Caulastrea*. *Caulastrea furcata* was not observed to bleach in 1998 in Palau.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Caulastrea*. We gathered supplemental information which provided the following details. In a study of warming-induced bleaching of over 100 coral species on the GBR in 2002, approximately 10 percent of *C. furcata* colonies were affected by bleaching, making it one of the least affected species in the study (Done *et al.*, 2003b). There is no information on the susceptibilities or vulnerabilities of *Caulastrea* to any other threats.

##### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Caulastrea* species to ocean warming, disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as "high" importance, and ocean acidification as "medium-high" importance, to corals. These were rated as the three most important threats to reef-building corals overall. *Caulastrea* has shown low levels or no thermal-induced bleaching in two studies, one reported in the SRR, and one reported above (Done *et al.*, 2003b). Thus, we conclude that an unstudied *Caulastrea* is likely to have low susceptibility to ocean warming. Although there is no other genus-level or species-specific information on the susceptibilities of *Caulastrea* species to disease and ocean acidification, the SRR rated them as "high" and "medium-high" importance to corals, respectively. Thus, we conclude that an unstudied *Caulastrea*

species is likely to have some susceptibility to disease and ocean acidification.

The SRR rated the trophic effects of fishing as “medium” importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Caulastrea* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation and nutrients as “low-medium” importance to corals overall. Although there is no genus-level or species-specific information on the susceptibilities of *Caulastrea* species to sedimentation and nutrients, there is no information suggesting they are not susceptible to these threats. Thus, we conclude that an unstudied *Caulastrea* species is likely to have some susceptibility to sedimentation and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Caulastrea* species is likely to have some susceptibility to sea-level rise. The SRR rated predation and ornamental trade (referred to in the proposed rule as Collection and Trade) as “low” importance to corals overall. There is no information on the effects of predation and collection and trade on *Caulastrea*, thus we conclude that *Caulastrea* likely has some susceptibility to predation and collection and trade.

In conclusion, an unstudied *Caulastrea* species is likely to have low susceptibility to ocean warming, and some susceptibility to disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade.

#### *Caulastrea echinulata*

##### Introduction

The SRR and SIR provided the following information on *C. echinulata*'s morphology and taxonomy. Morphology was described as elongated, closely compacted corallites on the ends of branches, and taxonomy was described as having no taxonomic issues but being

similar in appearance to *Caulastrea furcata*.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and indicated that there is moderate taxonomic uncertainty for *C. echinulata* and a moderate level of species identification uncertainty for this species. Veron (2014) states that *C. echinulata* is commonly confused with *C. furcata*, but the species can be identified by experts (Fenner, 2014b), thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *C. echinulata*'s distribution, habitat, and depth range. The distribution includes the Coral Triangle and GBR and a few nearby areas. Its primary habitat is horizontal substrates protected from wave action and with turbid water, which can occur in a variety of reef habitats, including at least upper reef slopes, mid-slopes, and lagoons. Its depth range is one to 20 meters.

The public comments did not provide any new or supplemental information on *C. echinulata*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 15 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 12.

##### Demographic Information

The SRR and SIR reported *C. echinulata*'s abundance as uncommon. The public comments did not provide any new or supplemental information on *C. echinulata*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *C. echinulata* occupied 0.34 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.3 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “rare,” and overall abundance was described as “uncommon.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from

total live coral cover trends and habitat types. For *C. echinulata*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by harder coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *C. echinulata* occurs in many areas affected by these broad changes, and likely has some susceptibility to local and global threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

##### Other Biological Information

The public comments and information we gathered did not provide any other biological information on this species.

##### Susceptibility to Threats

The SRR and SIR provided the following species-specific information on *C. echinulata*'s threats. Trade in *C. echinulata* is heavy. From 1999 to 2009, gross exports averaged 8,713 specimens annually, with the vast majority originating in Indonesia. Take quotas over that same period increased from 9,000 in 1999 to 10,670 in 2010. Some general (*i.e.*, family-level and coral-level) information was also provided for the effects of ocean warming, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *C. echinulata*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *C. echinulata*'s vulnerabilities as follows: Moderate vulnerability to ocean warming, disease, acidification, trophic effects of fishing, and nutrients, low vulnerability to sea

level rise and collection and trade, and unknown vulnerability to sedimentation and predation.

Public comments did not provide any new or supplemental information on *C. echinulata*'s threat susceptibilities. We gathered the following species-specific and genus-level supplemental information on this species' threat susceptibilities. *Caulastrea echinulata* has not been rated as moderately or highly susceptible to bleaching or disease, but this rating is not based on species-specific data (Carpenter *et al.*, 2008). Based on genus information described above, *C. echinulata* is likely to have low susceptibility to ocean warming, and likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the susceptibilities of *C. echinulata* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *C. echinulata*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm *C. echinulata* occurs in 15 Indo-Pacific ecoregions that encompass 12 countries' EEZs. The 12 countries are Australia, Brunei, China, Fiji, Indonesia, Japan, Malaysia, Palau, Papua New Guinea, Philippines, Solomon Islands, and Taiwan. The regulatory mechanisms relevant to *C. echinulata*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (25 percent with none limited in scope), coral collection (67 percent with 42 percent limited in scope), pollution control (42 percent with 8 percent limited in scope), fishing regulations on reefs (100 percent with 25 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *C. echinulata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 42 percent of coral collection laws are limited in scope and may not provide

substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *C. echinulata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *C. echinulata* are its uncommon abundance and that it is heavily traded. It listed factors that reduce potential extinction risk including that the species distribution is broad latitudinally, and that its preferred habitat type (turbid conditions) may provide some refuge from global threats such as bleaching (to which it may have relatively low susceptibility).

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *C. echinulata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. *Caulastrea echinulata* has low susceptibility to ocean warming-induced bleaching, based on species-specific and genus-level information. Its geographic distribution is mostly constrained to parts of the Coral Triangle and western equatorial Pacific Ocean—areas which are projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. For a species that is highly susceptible to climate change related threats, this range would exacerbate vulnerability to extinction but *C. echinulata* has low susceptibility. Vulnerability to extinction may be exacerbated by the severe nature of local

threats predicted within its range, however, *C. echinulata* is not highly susceptible to any local sources of impact either. Its depth range is from one to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes horizontal substrates protected from wave action and with turbid water, which can occur on at least upper reef slopes, mid-slopes, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. In addition, turbidity can mitigate against the effects of high irradiance by blocking it from the water column in turbid environments. Its absolute abundance of at least millions of colonies, combined with its low susceptibility to ocean warming, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. Further, its absolute abundance of at least tens of millions of colonies also provides buffering capacity against collection pressures for the purposes of international trade.

#### Listing Determination

In the proposed rule using the determination tool formula, *C. echinulata* was proposed for listing as threatened because of: Moderate vulnerability to ocean warming (ESA Factor E), disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E)); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *C. echinulata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity

of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *C. echinulata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Caulastrea echinulata*'s low sensitivity to bleaching and depth range down to 20 m, along with its preference for turbid water habitat, all combine to provide refuge from thermal stress and may decrease synergistic impacts from other threats;

(2) While *Caulastrea echinulata*'s distribution is mostly constrained to parts of the Coral Triangle and western equatorial Pacific Ocean, its distribution is spread over a large area across the Coral Triangle, southern Japan and Fiji. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(3) *Caulastrea echinulata*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. Its absolute abundance also provides buffering capacity against collection pressures for purposes of international trade. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and

worsen in severity and the species' exposure to the threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *C. echinulata* is not warranted for listing at this time under any of the listing factors.

#### Genus *Euphyllia*

##### Genus Introduction

The family Euphyllidae contains five genera, all in the Indo-Pacific, including *Euphyllia*. The genus *Euphyllia* contains eight species. The SRR and SIR provided no genus-level introductory information on *Euphyllia*.

##### Genus Susceptibility to Threats

The SRR and SIR provided the following information on the threat susceptibilities of the genus *Euphyllia*. *Euphyllia* species experienced high bleaching, but mortality is unknown, following the 1997/1998 mass bleaching event in Palau. In Indonesia, the family Euphyllidae had no prevalence of coral disease. When raised in acidified conditions, *Euphyllia paradivisa* showed little change in skeletal morphology, while *Galaxea* and *Stylophora* showed substantial skeletal change and *Pocillopora* died. The SRR reported that abundance of *Euphyllia* recruits was enhanced in areas where fish were excluded, indicating it may be more tolerant of the shaded conditions created by increased algal biomass in overfished areas. *Euphyllia divisa* was fairly sensitive to exposure to cyanide; concentrations at or below those used in cyanide fishing caused a progressive tissue detachment, microbial infection, and death. Large patches of *Euphyllia* species can form in turbid areas in Indonesia, suggesting a toleration of high sediment loads. *Euphyllia cristata* is heavily used in the aquarium trade with species-specific exports or quotas from Indonesia, Fiji, Malaysia, and Tonga. Actual reported annual exports from Indonesia alone averaged over 36,000 pieces from 2000 to 2008.

The public comments did not provide any new or supplemental information on the threat susceptibilities of the genus *Euphyllia*, except for a public comment on a study cited in the SRR on

the effects of ocean acidification on *E. paradivisa*, which is discussed in the description of that species below. We gathered supplemental information which provided the following. The 1998 Palau bleaching event affected at least three *Euphyllia* species (*E. divisa*, *E. glabrescens*, and *E. paraancora*), and all three species reported high levels of bleaching (Bruno *et al.*, 2001). *Euphyllia* was the largest live trade genus from 1985 to 1997 (Green and Shirley, 1999) and in 1999 (Bruckner, 2001). There is no other supplemental information on the effects of threats on the genus *Euphyllia*.

##### Genus Conclusion

Based on the information from the SRR, SIR, public comments, and supplemental information, we can make the following inferences about the susceptibilities of an unstudied *Euphyllia* species to ocean warming, disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade. The SRR rated ocean warming and disease as "high" importance, and ocean acidification as "medium-high" importance, to corals. These were rated as the three most important threats to reef-building corals overall. The one available study reporting the effects of ocean warming on *Euphyllia* reported high levels of bleaching. We conclude that an unstudied *Euphyllia* species is likely to have high susceptibility to ocean warming. Family Euphyllidae was found to be disease-free in Indonesia. However, this single study provides inadequate information to conclude low susceptibility to disease, thus we conclude that an unstudied *Euphyllia* species is likely to have some susceptibility to disease. The one available study on a *Euphyllia* species in acidified water did not show effects on skeletal growth. This is the Tibbits (2009) study on *E. paradivisa* that a public comment stated is flawed. As described below in the *E. paradivisa* species description below, we reviewed the study and we concur that the methods were flawed, thus the study does not provide an adequate basis to conclude low susceptibility. Therefore, we conclude that an unstudied *Euphyllia* species is likely to have some susceptibility to ocean acidification.

The SRR rated the trophic effects of fishing as "medium" importance, the fourth most important threat to corals overall. This threat was not addressed at the genus or species level in the SRR or SIR, because it is an ecosystem-level process. That is, removal of herbivorous fish from coral reef systems by fishing

alters trophic interactions by reducing herbivory on algae, thereby providing a competitive advantage for space to algae over coral. Thus, the SRR did not discuss this threat in terms of coral taxa, as its effects are difficult to distinguish between coral genera and species. Therefore, an unstudied *Euphyllia* species is likely to have some susceptibility to the trophic effects of fishing.

The SRR rated sedimentation and nutrients as “low-medium” importance to corals overall. One study reported *Euphyllia* tolerates turbid waters, suggesting tolerance of sedimentation, and one study suggested that *Euphyllia* may be tolerant of increased algae due to nutrients. However, these single studies provide inadequate information to conclude low susceptibilities, thus we conclude that an unstudied *Euphyllia* species is likely to have some susceptibility to sedimentation and nutrients. Sea-level rise was not addressed at the genus or species level in the SRR or SIR. Increasing sea levels may increase land-based sources of pollution due to inundation, resulting in changes to coral community structure, thus an unstudied *Euphyllia* species is likely to have some susceptibility to sea-level rise. Although there is no genus-level or species-specific information on the susceptibility of *Euphyllia* species to predation, there is no information suggesting they are not susceptible to these threats. Thus, we conclude that an unstudied *Euphyllia* species is likely to have some susceptibility to predation. Some *Euphyllia* species are heavily exploited in the ornamental trade, thus we conclude that an unstudied *Euphyllia* species is likely to have high susceptibility to collection and trade.

In conclusion, an unstudied *Euphyllia* species is likely to have high susceptibility to ocean warming and collection and trade, and some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, and predation.

#### *Euphyllia cristata*

##### Introduction

The SRR and SIR provided the following information on *E. cristata*'s morphology and taxonomy. Morphology was described as branching separate corallites without a shared wall but close together, and solitary polyps are common, and taxonomy was described as having no taxonomic issues.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there

are no known taxonomic problems for *E. cristata*, and a moderate level of species identification uncertainty. Veron (2014) states that *E. cristata* is sometimes confused with *Euphyllia glabrescens*. However, it can be identified by experts (Fenner, 2014b), thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *E. cristata*'s distribution, habitat, and depth range. *Euphyllia cristata*'s distribution is the central Indo-Pacific and the central Pacific. Its habitat includes most coral reef environments, and its depth range is one to 35 meters.

Public comments did not provide any new or supplemental information on *E. cristata*'s distribution. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 37 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 12. Public comments and information we gathered did not provide any more information on *E. cristata*'s habitat and depth range.

##### Demographic Information

The SRR and SIR reported *E. cristata*'s abundance as uncommon.

Public comments did not provide any new or supplemental information on *E. cristata*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *E. cristata* occupied 12.1 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.33 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as “common,” and overall abundance was described as “uncommon but conspicuous.” Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *E. cristata*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”)

was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison sub-section, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *E. cristata* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on limited species specific information.

##### Other Biological Information

The public comments and information we gathered did not provide any other biological information on this species.

##### Susceptibility to Threats

The SRR and SIR provided the following species-specific information on *E. cristata*'s threats. *Euphyllia cristata* is heavily used in the aquarium trade with species-specific exports or quotas from Indonesia, Fiji, Malaysia, and Tonga. Actual reported annual exports from Indonesia alone averaged over 36,000 pieces from 2000 to 2008. Genus-level information is provided for the effects on *Euphyllia* of ocean warming, disease, ocean acidification, land-based sources of pollution (sedimentation, nutrients, toxins, and salinity), predation, and collection/trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *E. cristata*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *E. cristata*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, predation, and collection and trade.

Public comments did not provide any new or supplemental information on *E. cristata*'s threat susceptibilities. We gathered supplemental species-specific and genus-level information on this

species' threat susceptibilities.

*Euphyllia cristata* was not rated as moderately or highly susceptible to bleaching or coral disease by Carpenter *et al.* (2008), but they did not have species-specific data. There are no studies of the effects of any threat on this species. Based on genus-level information presented above, *E. cristata* is likely to have high susceptibility to ocean warming and collection and trade, and some susceptibility to disease, ocean acidification, trophic effects of fishing, nutrients, sedimentation, sea-level rise, and predation.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *E. cristata*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm *E. cristata* occurs in 37 Indo-Pacific ecoregions that encompass 21 countries' EEZs. The 21 countries are Australia, Brunei, China, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), Indonesia, Japan, Malaysia, Maldives, Myanmar, Palau, Papua New Guinea, Philippines, Solomon Islands, Taiwan, Thailand, Timor-Leste, United States (CNMI, Guam), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *E. cristata*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (38 percent with five percent limited in scope), coral collection (62 percent with 29 percent limited in scope), pollution control (43 percent with 14 percent limited in scope), fishing regulations on reefs (100 percent with 14 percent limited in scope), and managing areas for protection and conservation (95 percent with none limited in scope). The most common regulatory mechanisms in place for *E. cristata* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *E. cristata*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase potential extinction risk for *E. cristata* include its heavy involvement in international trade combined with its rare existence but conspicuous colonies, suggesting it is vulnerable to overexploitation. *Euphyllia cristata* appears to be susceptible to bleaching. The SRR noted that its geographic distribution is moderate, although wider than its congeners under consideration in this review.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *E. cristata*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes many of the coral reef ecoregions from the northern Indian Ocean through the western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is from one to 35 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than

those in which the species occurs. Its habitat includes most coral reef environments. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. Further, its absolute abundance of at least tens of millions of colonies also provides buffering capacity against collection pressures for the purposes of international trade.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *E. cristata* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); moderate overall distribution (based on moderate geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *E. cristata* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *E. cristata*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Euphyllia cristata*'s distribution in the northern Indian Ocean, central Indo-Pacific, and central Pacific is spread

over a vast area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future;

(2) *Euphyllia cristata*'s absolute abundance is at least tens of millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. Its absolute abundance also provides buffering capacity against collection pressures for purposes of international trade. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

(3) *Euphyllia cristata* occurs from one to 35 meters of depth which provides vertical moderation of exposure to threats and increases the absolute area of potential occupancy within the species range, therefore buffering against extinction risk.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *E.*

*cristata* is not warranted for listing at this time under any of the listing factors.

### *Euphyllia paraancora*

#### Introduction

The SRR and SIR provided the following information on *E. paraancora*'s morphology and taxonomy. Morphology was described as branching separate corallites without a shared wall, and tentacles have anchor-shaped ends. Taxonomy was described as having no taxonomic issues but tentacles are similar to *Euphyllia ancora*, and the skeleton is the same as *Euphyllia glabrescens*, *Euphyllia paraglabrescens*, and *Euphyllia paradivisa*.

Public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *E. paraancora*, but there is a low level of species identification uncertainty for this species. The species can be easily identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

#### Spatial Information

The SRR and SIR provided the following information on *E. paraancora*'s distribution, habitat, and depth range. *Euphyllia paraancora* is found in the Coral Triangle, Taiwan, the Mariana Islands, New Caledonia and Vanuatu. The SIR reports that colonies found in Guam were in turbid environments. Its habitat includes reef environments protected from wave action, including at least upper reef slopes, mid-slopes, lower reef slopes, and lagoons, from three to 30 m deep.

One public comment confirmed the presence of *E. paraancora* in Guam. We gathered supplemental information, including Veron (2014), which reports that this species is confirmed in 19 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 15. *Euphyllia paraancora* has been reported in water as deep as 70 m (Carpenter *et al.*, 2008; Rooney *et al.*, 2012). Based on all the available information, its habitat includes least upper reef slopes, mid-slopes, lower reef slopes, lagoons, and mesophotic areas, from three to 70 m deep.

#### Demographic Information

The SRR and SIR reported *E. paraancora*'s abundance as uncommon. However, it has reportedly been found in large monospecific stands at six to 8 m depth in Taiwan.

Public comments did not provide any new or supplemental information on *E. paraancora*'s abundance. We gathered supplemental information that provides the following. *Euphyllia paraancora* has been reported from large monospecific stands at 60 to 70 m depth in Saipan (Rooney *et al.*, 2012). Veron (2014) reports that *E. paraancora* occupied 1.9 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.46 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "uncommon," and overall abundance was also described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *E. paraancora*, the overall decline in abundance ("Percent Population Reduction") was estimated at 36 percent, and the decline in abundance before the 1998 bleaching event ("Back-cast Percent Population Reduction") was estimated at 14 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *E. paraancora* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible based on limited species specific information.

#### Other Biological Information

The public comments and information we gathered did not

provide any other biological information on this species.

#### Susceptibility to Threats

To describe *E. paraancora*'s threat susceptibilities, the SRR and SIR provided the following species-specific information on *E. paraancora*'s threats. *Euphyllia paraancora* and its congeners experienced high bleaching but mortality is unknown following the 1997/1998 mass bleaching event in Palau (Bruno *et al.*, 2001). *Euphyllia paraancora* in Taiwan contained both Clades C and D zooxanthellae, with Clade D primarily in stressful environments like shallow waters and reef edges. *Euphyllia paraancora* is specifically listed in the CITES databases with a 2008 annual export quota of ~ 5000 (up from 1000 in 2004) "maricultured" pieces from Indonesia although the meaning of "maricultured" is unclear. Genus-level information is provided for the effects on *Euphyllia* of ocean warming, ocean acidification, disease, land-based sources of pollution (sedimentation, nutrients, toxins, and salinity), predation, and collection/trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *E. paraancora*. We interpreted threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *E. paraancora*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, and low vulnerability to sedimentation, sea level rise, and collection and trade.

Public comments did not provide any new or supplemental information on *E. paraancora*'s threats susceptibilities. We gathered supplemental species-specific and genus-level information on this species' threat susceptibilities. *Euphyllia paraancora* was not rated as moderately or highly susceptible to bleaching or disease by Carpenter *et al.* (2008), but they did not have species-specific data. In Palau in 2000, *E. paraancora* had high levels of bleaching, but an unknown level of mortality. In that event, 48 percent of all coral colonies of all species were bleached, with bleaching of different genera and species ranging from none to very high, and mortality from none to near 100 percent (Bruno *et al.*, 2001). There are no other studies of the effects of any threat on this species. Combined with genus-level information presented above, *E. paraancora* is likely to have high susceptibility to ocean warming and collection and trade. Further based on genus level information, *E. paraancora* can be predicted to have

some susceptibility to disease, ocean acidification, trophic effects of fishing, nutrients, sedimentation, sea-level rise, and predation.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *E. paraancora*. We received criticism of that approach in public comments and in response we present a species-specific analysis of regulatory mechanisms in this final rule. Records confirm that *Euphyllia paraancora* occurs in 19 Indo-Pacific ecoregions that encompass 16 countries' EEZs. The 16 countries Australia, Brunei, China, Federated States of Micronesia, France (French Pacific Island Territories), Indonesia, Japan, Malaysia, Palau, Papua New Guinea, Philippines, Solomon Islands, Taiwan, Timor-Leste, United States (CNMI, Guam), and Vietnam. The regulatory mechanisms relevant to *E. paraancora*, described first as the percentage of the above countries that utilize them to any degree, and second as the percentage of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (38 percent with none limited in scope), coral collection (63 percent with 25 percent limited in scope), pollution control (44 percent with 19 percent limited in scope), fishing regulations on reefs (100 percent with 19 percent limited in scope), and managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *E. paraancora* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 25 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *E. paraancora*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase potential extinction risk for *E. paraancora* include its heavy involvement in international trade combined with its

rare existence but conspicuous colonies, suggesting it is vulnerable to overexploitation. The species appears bleaching-susceptible. Its geographic distribution is also somewhat restricted, centered in the threat-prone Coral Triangle Region.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *E. paraancora*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution occurs in the Coral Triangle, the western equatorial Pacific Ocean, the Mariana Islands, and New Caledonia. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range goes down to 70 meters which stretches into the mesophotic zone. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes at least upper reef slopes, mid-slopes, lower reef slopes, lagoons, and mesophotic areas. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its absolute abundance of at least millions of colonies, combined with spatial

variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. Further, its absolute abundance of at least tens of millions of colonies also provides buffering capacity against collection pressures for the purposes of international trade.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *E. paraancora* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); wide overall distribution (based on moderate geographic distribution and wide depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *E. paraancora* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *E. paraancora*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus is not warranted for listing at this time, because:

(1) *Euphyllia paraancora*'s depth distribution of three to 70 m is exceptionally broad and deep for most reef-building coral species. The ability to occupy a broad range of depths likely provides refugia from threats that may be more severe in shallow environments because irradiance is usually lower at depths at the deeper end of this species' range. It also increases the absolute area of potential occupancy throughout the species range. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not

occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future; and

(2) *Euphyllia paraancora*'s absolute abundance is at least millions of colonies, providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. Its absolute abundance also provides buffering capacity against collection pressures for purposes of international trade. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response.

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future as global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *E. paraancora* is not warranted for listing at this time under any of the listing factors.

#### *Euphyllia paradivisa*

##### Introduction

The SRR and SIR provided the following information on *E. paradivisa*'s morphology and taxonomy. Morphology was described as branching separate corallites without a shared wall and branching tentacles. The taxonomy was described as having no taxonomic issues but having tentacles similar to *Euphyllia divisa* and skeleton that is the same as *Euphyllia glabrescens*, *Euphyllia*

*paraglabrescens*, and *Euphyllia paraancora*.

The public comments and information we gathered did not provide any new or supplemental information on morphology, and confirmed that there are no known taxonomic problems for *E. paradivisa*, and a low level of species identification uncertainty for this species. Veron (2014) states that *E. paradivisa* is very distinctive. The species can be easily identified by experts, thus we conclude that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *E. paradivisa*'s distribution, habitat, and depth range. *Euphyllia paradivisa*'s distribution is restricted to the Coral Triangle, and its habitat is shallow or mid-slope reef environments protected from wave action, from five to 20 meters depth.

The public comments did not provide any new or supplemental information on *E. paradivisa*'s distribution. We gathered supplemental information, including Veron (2014) which reports that *E. paradivisa* is confirmed in eight of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional eight. Fenner (2013a) reported *E. paradivisa* (supported by photographs), from American Samoa at about 25 m deep protected from wave action. Veron (2014) reports it from American Samoa based on that record. Thus, based on all the available information, *E. paradivisa*'s habitat includes environments protected from wave action on at least upper reef slopes, mid-slope terraces, and lagoons in depths ranging from two to 25 m depth.

##### Demographic Information

The SRR and SIR reported that *E. paradivisa*'s abundance is uncommon. The public comments did not provide any new or supplemental information on *E. paradivisa*'s abundance. We gathered supplemental information, including Veron (2014) which reported that *E. paradivisa* occupied 0.2 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.5 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "rare," and overall abundance was described as "uncommon." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species

Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *E. paradivisa*, the overall decline in abundance (“Percent Population Reduction”) was estimated at 38 percent, and the decline in abundance before the 1998 bleaching event (“Back-cast Percent Population Reduction”) was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *E. paradivisa* occurs in many areas affected by these broad changes, and likely has some susceptibility to both global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

#### Other Biological Information

The public comments and information we gathered did not provide any other biological information on this species.

#### Susceptibility to Threats

To describe *E. paradivisa*’s threat susceptibilities, the SRR and SIR provided genus-level information for the effects on *Euphyllia* of ocean warming, disease, acidification, sedimentation, predation, and collection and trade. The SRR and SIR also provided the following species-specific information on *E. paradivisa*’s threats. When raised in acidified conditions, *E. paradivisa* showed little change in skeletal morphology, while *Galaxea* and *Stylophora* showed substantial skeletal change and *Pocillopora* died. *Euphyllia paradivisa* is specifically listed in the CITES databases with annual export quotas of up to 2380 “maricultured” pieces from Indonesia, although the

meaning of “maricultured” is unclear. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *E.*

*paradivisa*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *E. paradivisa*’s vulnerabilities to threats as follows: High vulnerability to ocean warming, moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown vulnerability to predation.

The public comments provided the following supplemental information on *E. paradivisa*’s threat susceptibilities. A public comment stated that the SRR appeared to rely solely upon collection and trade to rate the extinction risk of this species, subsequently leading to the proposed Endangered listing. However, the SRR (and the Determination Tool in the proposed rule) both considered the susceptibilities and vulnerabilities of this species to multiple threats to help determine its extinction risk and proposed listing status. Likewise, as explained in the Determination Framework section above, this final rule considers the susceptibilities, exposures, and vulnerabilities of each species to the nine major threats to determine its extinction risk and listing status, including for *E. paradivisa*.

The public comment also stated that an unpublished study cited by the SRR on the effects of ocean acidification on *E. paradivisa* (Tibbits, 2009) is flawed. The study reported that the skeletal morphology of *E. paradivisa* specimens kept in acidified conditions over a three month period “did not change noticeably.” We reviewed the study, and we concur with the public comment, in that the methods used in the study to lower pH were flawed, thus the results should not be considered reliable information on the potential effects of ocean acidification on *E. paradivisa*.

We gathered the following species-specific supplemental information on this species’ threat susceptibilities. *Euphyllia paradivisa* was not rated as moderately or highly susceptible to bleaching and disease, but these ratings are not based on species-specific data (Carpenter *et al.*, 2008). Based on the genus and species-specific information described above, *E. paradivisa* is likely to have high susceptibility to ocean warming and collection and trade, some susceptibility to disease, acidification, trophic effects of fishing, nutrients, and predation, and low susceptibility to sedimentation and sea-level rise. The available information does not support

more precise ratings of the susceptibilities of *E. paradivisa* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanism or conservation efforts for *E. paradivisa*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm that *Euphyllia paradivisa* occurs in eight Indo-Pacific ecoregions that encompass 15 countries’ EEZs. The 15 countries are Brunei, Fiji, France (French Pacific Island Territories), Indonesia, Malaysia, New Zealand (Tokelau), Niue, Papua New Guinea, Philippines, Samoa, Timor-Leste, Tonga, Tuvalu, United States (American Samoa), and Vietnam. The regulatory mechanisms relevant to *E. paradivisa*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (33 percent with none limited in scope), coral collection (80 percent with 40 percent limited in scope), pollution control (53 percent with 20 percent limited in scope), fishing regulations on reefs (100 percent with 20 percent limited in scope), managing areas for protection and conservation (100 percent with none limited in scope). The most common regulatory mechanisms in place for *E. paradivisa* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also common for the species, but 40 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are much less common regulatory mechanisms for the management of *E. paradivisa*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species’ vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated that factors that increase the potential extinction risk for *E. paradivisa* include its heavy involvement in international trade combined with its rare existence but conspicuous colonies, suggesting it is vulnerable to overexploitation. The species appears bleaching-susceptible. Its geographic distribution is also

somewhat restricted, centered in the threat-prone Coral Triangle Region. No known factors were noted by the BRT to reduce the extinction risk of this species.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *E. paradivisa*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution is mostly limited to parts of the Coral Triangle. Despite the large number of islands and environments that are included in the species' range, this range exacerbates vulnerability to extinction over the foreseeable future because it is mostly limited to an area projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century. Its depth range of two to 25 meters moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance than surface waters, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes environments protected from wave action on at least upper reef slopes, mid-slope terraces, and lagoons. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range, moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable

future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time. However, its qualitative abundance is described as rare, which can exacerbate its vulnerability given its restricted range.

#### Listing Determination

In the proposed rule using the determination tool formula, *E. paradivisa* was proposed for listing as endangered because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); uncommon generalized range wide abundance (E); narrow overall distribution (based on narrow geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed our listing determination of *E. paradivisa* from endangered to threatened. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information provided above on *E. paradivisa*'s spatial structure, demography, threat susceptibilities, and management indicate that it is likely to become endangered throughout its range within the foreseeable future, and thus warrants listing as threatened at this time, because:

(1) *Euphyllia paradivisa* is susceptible to warming-induced bleaching (ESA Factor E), disease (C), ocean acidification (E), trophic effects of fishing (A), nutrients (A, E), predation (C), and collection and trade (B). These threats are expected to continue and worsen into the future. In addition, the species has inadequate existing regulatory mechanisms for global threats (D).

(2) *Euphyllia paradivisa*'s distribution is limited mostly to the Coral Triangle, which is projected to have the most rapid and severe impacts from climate change and localized human impacts for coral reefs over the 21st century, as described in the Threats Evaluation. Multiple ocean warming events have already occurred within the Coral Triangle that suggest future ocean warming events may be more severe than average in this part of the world. A range constrained to this particular

geographic area that is likely to experience severe and increasing threats indicates that a high proportion of the population of this species is likely to be exposed to those threats over the foreseeable future; and

(3) *Euphyllia paradivisa*'s semi-quantitative abundance is rare. Considering the limited range of this species in an area where severe and increasing impacts are predicted, this level of abundance leaves the species vulnerable to becoming of such low abundance within the foreseeable future that it may be at risk from depensatory processes, environmental stochasticity, or catastrophic events, as explained in more detail in the Corals and Coral Reefs and Risk Analyses sections.

The combination of these characteristics and projections of future threats indicates that the species is likely to be in danger of extinction within the foreseeable future throughout its range and warrants listing as threatened at this time due to factors A, C, D, and E.

The available information above on *E. paradivisa*'s spatial structure, demography, threat susceptibilities, and management also indicate that the species is not currently in danger of extinction and thus does not warrant listing as Endangered because:

(1) While *E. paradivisa*'s range is mostly within the Coral Triangle, which increases its extinction risk as described above, its habitat includes environments protected from wave action on at least upper reef slopes, mid-slope terraces, and lagoons. This moderates vulnerability to extinction currently because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time, as described in more detail in the Coral Habitat and Threats Evaluation sections. There is no evidence to suggest that the species is so spatially fragmented that depensatory processes, environmental stochasticity, or the potential for catastrophic events currently pose a high risk to the survival of the species; and

(2) While *Euphyllia paradivisa*'s qualitative abundance is rare, its absolute abundance is millions of colonies, which allows for some variation in the responses of individuals to threats. There is no evidence of depensatory processes such as reproductive failure from low density of reproductive individuals and genetic processes such as inbreeding affecting this species. Thus, its absolute abundance indicates it is currently able

to avoid high mortality from environmental stochasticity, and mortality of a high proportion of its population from catastrophic events. The combination of these characteristics indicates that the species does not exhibit the characteristics of one that is currently in danger of extinction, as described previously in the Risk Analyses section, and thus does not warrant listing as endangered at this time.

Range-wide, a multitude of conservation efforts are already broadly employed that are likely benefiting *E. paradivisa*. However, considering the global scale of the most important threats to the species, and the ineffectiveness of conservation efforts at addressing the root cause of global threats (i.e., greenhouse gas emissions), we do not believe that any current conservation efforts or conservation efforts planned in the future will result in affecting the species status to the point at which listing is not warranted.

#### Genus *Physogyra*

##### Genus Introduction

The family Euphyllidae consists of five genera: *Euphyllia*, *Catalaphyllia*, *Nemanzophyllia*, *Plerogyra*, and *Physogyra*. The genus *Physogyra* is monospecific, meaning it only includes *P. lichtensteini* (Veron, 2000), so there is no need to provide genus-level information.

#### *Physogyra lichtensteini*

##### Introduction

The SRR and SIR provided the following information on *P. lichtensteini*'s morphology and taxonomy. Morphology was described as massive or thick, platy and meandroid forms with short, widely separated valleys, and taxonomy was described as having no taxonomic issues, but being similar to *Plerogyra sinuosa*.

The public comments did not provide any new or supplemental information on morphology or taxonomy. We gathered supplemental information, including Veron (2014), which states that *P. lichtensteini* is one of the world's most distinctive species. In addition, Veron (2000; 2014) considers the species valid, thus we conclude it can be identified by experts and that the distribution and abundance information described below for this species is sufficiently reliable (Fenner, 2014b).

##### Spatial Information

The SRR and SIR provided the following information on *P. lichtensteini*'s distribution, habitat, and

depth range. *Physogyra lichtensteini* is distributed from the Red Sea and the Indian Ocean to the western and central Pacific Ocean. The SRR described *P. lichtensteini*'s habitat as turbid reef environments, crevices and overhangs, especially in turbid water with tidal currents, and shallow but shaded waters such as caves on the GBR, with a depth range of one to 20 meters. The SIR added that the species is also known to occur in clear water.

The public comments did not provide any new or supplemental information on *P. lichtensteini*'s distribution. We gathered supplemental information, including Veron (2014), which reports that *P. lichtensteini* is confirmed in 54 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 18. In addition to shaded habitats, including turbid and clear water, *P. lichtensteini* also occurs in full sun (D. Fenner, personal comm.), thus the species occurs in variety of habitats. Thus, based on all the available information, *P. lichtensteini*'s occurs in both turbid and clear upper reef slopes, mid-slopes, lower reef crests, reef flats, lagoons, and caves in depth ranging from one to 20 m depth.

##### Demographic Information

The SRR and SIR reported *P. lichtensteini*'s abundance as common in turbid water and crevices and overhangs, especially in turbid water with tidal currents.

The public comments did not provide any new or supplemental information on *P. lichtensteini*'s abundance. We gathered supplemental information, including Veron (2014), which reports that *P. lichtensteini* occupied 30.9 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.31 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as "common," and overall abundance was described as "common in protected habitats." Veron did not infer trends in abundance from these data. As described in the Indo-Pacific Species Determinations introduction above, based on results from Richards *et al.* (2008) and Veron (2014), the absolute abundance of this species is likely at least tens of millions of colonies.

Carpenter *et al.* (2008) extrapolated species abundance trend estimates from total live coral cover trends and habitat types. For *P. lichtensteini*, the overall decline in abundance ("Percent Population Reduction") was estimated at 37 percent, and the decline in abundance before the 1998 bleaching

event ("Back-cast Percent Population Reduction") was estimated at 15 percent. However, as summarized above in the Inter-basin Comparison subsection, live coral cover trends are highly variable both spatially and temporally, producing patterns on small scales that can be easily taken out of context. Thus, quantitative inferences to species-specific trends should be interpreted with caution. At the same time, an extensive body of literature documents broad declines in live coral cover and shifts to reef communities dominated by hardier coral species or algae over the past 50 to 100 years (Birkeland, 2004; Fenner, 2012; Pandolfi *et al.*, 2003; Sale and Szmant, 2012). These changes have likely occurred, and are occurring, from a combination of global and local threats. Given that *P. lichtensteini* occurs in many areas affected by these broad changes, and likely has some susceptibility to global and local threats, we conclude that it is likely to have declined in abundance over the past 50 to 100 years, but a precise quantification is not possible due to the limited species-specific information.

##### Other Biological Information

The SRR and SIR provided the following information on *P. lichtensteini*'s life history. *Physogyra lichtensteini* is a gonochoric broadcast spawner. Larvae do not contain zooxanthellae. The public comments provided no additional biological information. We gathered supplemental information, including the following: Darling *et al.* (2012) found that *P. lichtensteini* has a "stress-tolerant" life history strategy, defined as slow growth and large colonies which can survive through stress and disturbances.

##### Susceptibility to Threats

The SRR and SIR provided the following species-specific information on *P. lichtensteini*'s threats. *Physogyra lichtensteini* has been identified as vulnerable to extinction due to its high bleaching rate, low diversity of its genus, and narrow habitat range. The species bleached at 31°C in Palau in 1998. *Physogyra lichtensteini* contains Clade C zooxanthellae in the South China Sea. *Physogyra lichtensteini* is preyed upon on by butterflyfish in Indonesia. Since *P. lichtensteini* prefers turbid waters the risk of sediment impacts are low. The genus *Physogyra* is heavily traded, primarily exported from Indonesia. Between 1999 and 2010, the trade quota for Indonesia has been approximately 10,000 specimens annually. The SRR and SIR also provided genus-level and coral-level

information for the effects on *Physogyra* of thermal stress, acidification, disease, predation, sedimentation, nutrients, and collection and trade. The SRR and SIR did not provide any other species-specific information on the effects of these threats on *P. lichtensteini*. We interpreted the threat susceptibility and exposure information from the SRR and SIR in the proposed rule for *P. lichtensteini*'s vulnerabilities as follows: High vulnerability to ocean warming; moderate vulnerability to disease, ocean acidification, trophic effects of fishing, and nutrients, low vulnerability to sedimentation, sea level rise, and collection and trade, and unknown vulnerability to predation.

Public comments did not provide any new or supplemental information on *P. lichtensteini*'s threat susceptibilities. We gathered supplemental information, which provided the following species-specific and genus-level information on this species' threat susceptibilities. *Physogyra lichtensteini* was not rated as moderately or highly susceptible to bleaching and coral disease by Carpenter *et al.* (2008), but they did not have species-specific data. In the western Indian Ocean in 1998–2005, the genus *Physogyra* (which only includes *P. lichtensteini*) had a bleaching index of 16.7 for eight countries, which was 19th highest of the 45 genera recorded, and 45 percent of the highest value. In this study, *P. lichtensteini* was identified as vulnerable to extinction due to its high bleaching rate, low diversity of its genus, and narrow habitat range, and the genus *Physogyra* was rated as having the fifth highest extinction risk of the 45 genera in the study (McClanahan *et al.*, 2007a). In Palau in 2000, *P. lichtensteini* experienced very high levels of bleaching and mortality. In that event, 48 percent of all coral colonies of all species were bleached, with bleaching of different genera and species ranging from none to very high, and mortality from none to near 100 percent (Bruno *et al.*, 2001). There are no other studies of the effects of threats on this genus or species. Based on the species-specific information above, *P. lichtensteini* is likely highly susceptible to ocean warming. Based on the threat susceptibility information for other reef-building coral genera in this final rule, *P. lichtensteini* likely has some susceptibility to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade. The available information does not support more precise ratings of the

susceptibilities of *P. lichtensteini* to the threats.

#### Regulatory Mechanisms

In the proposed rule, we did not provide any species-specific information on the regulatory mechanisms or conservation efforts for *P. lichtensteini*. Criticisms of our approach received during public comment led us to attempt the following analysis of regulatory mechanisms on a species basis. Records confirm *P. lichtensteini* occurs in 54 Indo-Pacific ecoregions that encompass 35 countries' EEZs. The 35 countries are Australia, Brunei, China, Egypt, Federated States of Micronesia, Fiji, France (French Pacific Island Territories), India (including Andaman and Nicobar Islands), Indonesia, Israel, Japan, Jordan, Kenya, Madagascar, Malaysia, Maldives, Marshall Islands, Mauritius, Myanmar, Palau, Papua New Guinea, Philippines, Saudi Arabia, Seychelles, Solomon Islands, Sri Lanka, Sudan, Taiwan, Tanzania, Thailand, Timor-Leste, United Kingdom (British Indian Ocean Territory), United States (PRIAs), Vanuatu, and Vietnam. The regulatory mechanisms relevant to *P. lichtensteini*, described first as the percentage of the above countries that utilize them to any degree and second, as the percentages of those countries whose regulatory mechanisms may be limited in scope, are as follows: General coral protection (29 percent with 9 percent limited in scope), coral collection (57 percent with 29 percent limited in scope), pollution control (43 percent with 9 percent limited in scope), fishing regulations on reefs (89 percent with 20 percent limited in scope), managing areas for protection and conservation (97 percent with 11 percent limited in scope). The most common regulatory mechanisms in place for *P. lichtensteini* are reef fishing regulations and area management for protection and conservation. Coral collection and pollution control laws are also somewhat utilized for the species, but 29 percent of coral collection laws are limited in scope and may not provide substantial protection. General coral protection laws are less common regulatory mechanisms for the management of *P. lichtensteini*.

#### Vulnerability to Extinction

As explained above in the Risk Analyses section, a species' vulnerability to extinction results from the combination of its spatial and demographic characteristics, threat susceptibilities, and consideration of the baseline environment and future projections of threats. The SRR stated factors that increase the potential

extinction risk for *P. lichtensteini* are its high bleaching rate and that it's heavily collected. It listed factors that reduce potential extinction risk including that *P. lichtensteini* has a wide latitudinal distribution, is common, and tolerates difficult (turbid) environments.

Subsequent to the proposed rule, we received and gathered supplemental species- or genus-specific information, described above, that expands our knowledge regarding the species abundance, distribution, and threat susceptibilities. We developed our assessment of the species' vulnerability to extinction using all the available information. As explained in the Risk Analyses section, our assessment in this final rule emphasizes the ability of the species' spatial and demographic traits to moderate or exacerbate its vulnerability to extinction, as opposed to the approach we used in the proposed rule, which emphasized the species' susceptibility to threats.

The following characteristics of *P. lichtensteini*, in conjunction with the information described in the Corals and Coral Reefs section, Coral Habitat subsection, and Threats Evaluation section above, affect its vulnerability to extinction currently and over the foreseeable future. Its geographic distribution includes most of the coral reef ecoregions in the Indian Ocean and western and central Pacific Ocean. Its geographic distribution moderates vulnerability to extinction because some areas within its range are projected to have less than average warming and acidification over the foreseeable future, including the western Indian Ocean, the central Pacific, and other areas, so portions of the population in these areas will be less exposed to severe conditions. Its depth range is one to 20 meters. This moderates vulnerability to extinction over the foreseeable future because deeper areas of its range will usually have lower irradiance, and acidification is generally predicted to accelerate most in waters that are deeper and cooler than those in which the species occurs. Its habitat includes both turbid and clear upper reef slopes, mid-slopes, lower reef crests, reef flats, lagoons, and caves. This moderates vulnerability to extinction over the foreseeable future because the species is not limited to one habitat type but occurs in numerous types of reef environments that will, on local and regional scales, experience highly variable thermal regimes and ocean chemistry at any given point in time. Its abundance of at least tens of millions of colonies, combined with spatial variability in ocean warming and acidification across the species range,

moderates vulnerability to extinction because the increasingly severe conditions expected in the foreseeable future will be non-uniform and therefore will likely be a large number of colonies that are either not exposed or do not negatively respond to a threat at any given point in time.

#### Listing Determination

In the proposed rule using the determination tool formula approach, *P. lichtensteini* was proposed for listing as threatened because of: High vulnerability to ocean warming (ESA Factor E); moderate vulnerability to disease (C) and acidification (E); common generalized range wide abundance (E); wide overall distribution (based on wide geographic distribution and moderate depth distribution (E); and inadequacy of existing regulatory mechanisms (D).

In this final rule, we changed the listing determination for *P. lichtensteini* from threatened to not warranted. We made this determination based on a more species-specific and holistic assessment of whether this species meets the definition of either a threatened or endangered coral largely in response to public comments, including more appropriate consideration of the buffering capacity of this species' spatial and demographic traits to lessen its vulnerability to threats. Thus, based on the best available information above on *P. lichtensteini*'s spatial structure, demography, threat susceptibilities, and management, none of the five ESA listing factors, alone or in combination, are causing this species to be likely to become endangered throughout its range within the foreseeable future, and thus it is not warranted for listing at this time, because:

(1) *Physogyra lichtensteini*'s distribution across the Red Sea, Indian Ocean and most of the Pacific is spread over a very large area. While some areas within its range are projected to be affected by warming and acidification, other areas are projected to have less than average warming and acidification, including the western Indian Ocean, the central Pacific, and other areas. This distribution and the heterogeneous habitats it occupies reduce exposure to any given threat event or adverse condition that does not occur uniformly throughout the species range. As explained above in the Threats Evaluation section, we have not identified any threat that is expected to occur uniformly throughout the species range within the foreseeable future);

(2) *Physogyra lichtensteini*'s total absolute abundance is at least tens of

millions of colonies providing buffering capacity in the form of absolute numbers of colonies and variation in susceptibility between individual colonies. As discussed in the Corals and Coral Reefs section above, the more colonies a species has, the lower the proportion of colonies that are likely to be exposed to a particular threat at a particular time, and all individuals that are exposed will not have the same response; and

Notwithstanding the projections through 2100 that indicate increased severity over time of the three high importance threats, the combination of these biological and environmental characteristics indicates that the species possesses sufficient buffering capacity to avoid being in danger of extinction within the foreseeable future throughout its range. It is possible that this species' extinction risk may increase in the future if global threats continue and increase in severity and the species exposure to threats increases throughout its range. Should the species experience reduced abundance or range constriction of a certain magnitude, the ability of these characteristics to moderate exposure to threats will diminish. However, the species is not likely to become of such low abundance or so spatially fragmented as to be in danger of extinction due to compensatory processes, the potential effects of environmental stochasticity, or the potential for mortality from catastrophic events within the foreseeable future throughout its range. Therefore, *P. lichtensteini* is not warranted for listing at this time under any of the listing factors.

#### Summary of Determinations

In this final rule, we are responsible for determining whether each of the proposed coral species meet the definition of either threatened or endangered under the ESA based on the best available information including that which supported the proposed rule, and public comments received and information we gathered since the proposed rule was published. Section 4(b)(1)(A) of the ESA requires us to make listing determinations based solely on the best scientific and commercial data available after conducting reviews of the statuses of the species and after taking into account efforts being made by any state or foreign nation to protect the species. We conclude that conservation efforts are not protecting any of the coral species determined to be warranted for listing in this final rule in a way that would reduce extinction risk such that a threatened determination would no

longer be warranted. Finally, section 4(b)(1)(B) of the ESA requires us to give consideration to species which (1) have been designated as requiring protection from unrestricted commerce by any foreign nation, or (2) have been identified as in danger of extinction, or likely to become so within the foreseeable future, by any state agency or by any agency of a foreign nation. All stony corals are listed under Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora, which regulates international trade of species to ensure survival. *Dendrogyra cylindrus*, which we are listing as threatened, is also listed as threatened by the State of Florida and all stony corals are protected under the U.S. Virgin Islands Indigenous and Endangered Species Act of 1990. All of the corals in this final rule, including those we are listing under the ESA, are listed in the IUCN Red List of Threatened Species as vulnerable, endangered, or critically endangered. The final rule takes into consideration this information in its listing determinations.

In the proposed rule we determined that 12 species warranted listing as endangered: five in the Caribbean (*Dendrogyra cylindrus*, *Orbicella annularis*, *Orbicella faveolata*, *Orbicella franki*, and *Mycetophyllia ferox*); and seven in the Indo-Pacific (*Millepora foveolata*, *Pocillopora elegans* (eastern Pacific), *Acropora jacquelineae*, *Acropora lokani*, *Acropora rudis*, *Anacropora spinosa*, and *Euphyllia paradivisa*). We also determined that 54 species warranted listing as threatened: two in the Caribbean (*Agaricia lamarcki* and *Dichocoenia stokesii*); and 52 in the Indo-Pacific (*Millepora tuberosa*, *Pocillopora danae*, *Pocillopora elegans* (Indo-Pacific), *Seriatorpora aculeata*, *Acropora aculeus*, *Acropora acuminata*, *Acropora aspera*, *Acropora dendrum*, *Acropora donei*, *Acropora globiceps*, *Acropora horrida*, *Acropora listeri*, *Acropora microclados*, *Acropora palmerae*, *Acropora paniculata*, *Acropora pharaonis*, *Acropora polystoma*, *Acropora retusa*, *Acropora speciosa*, *Acropora striata*, *Acropora tenella*, *Acropora vaughani*, *Acropora verweyi*, *Anacropora puertogalerae*, *Astreopora cucullata*, *Isopora crateriformis*, *Isopora cuneata*, *Montipora angulata*, *Montipora australiensis*, *Montipora calcarea*, *Montipora caliculata*, *Montipora dilatata/flabellata/turgescens*, *Montipora lobulata*, *Montipora patula/verrilli*, *Alveopora allingi*, *Alveopora fenestrata*, *Alveopora verrilliana*, *Porites horizontalata*, *Porites napopora*, *Porites*

*nigrescens*, *Acanthastrea brevis*, *Acanthastrea hemprichii*, *Acanthastrea ishingakiensis*, *Acanthastrea regularis*, *Pachyseris rugosa*, *Pectinia allicornis*, *Barabattoia laddi*, *Pavona diffluens*, *Caulastrea echinulata*, *Euphyllia cristata*, *Euphyllia paraancora*, and *Physogyra lichtensteini*). Finally, we determined that two species in the Caribbean currently listed as threatened (*Acropora palmata* and *Acropora cervicornis*) warranted reclassification as endangered.

In this final rule we have determined that no species warrants listing as endangered. We have determined the following 20 species warrant listing as threatened: five in the Caribbean (*Dendrogyra cylindrus*, *Orbicella annularis*, *Orbicella faveolata*, *Orbicella franksi*, and *Mycetophyllia ferox*); and 15 in the Indo-Pacific (*Acropora globiceps*, *Acropora jacquelineae*, *Acropora lokani*, *Acropora pharaonis*, *Acropora retusa*, *Acropora rudis*, *Acropora speciosa*, *Acropora tenella*, *Anacropora spinosa*, *Euphyllia paradivisa*, *Isopora crateriformis*, *Montipora australiensis*, *Pavona diffluens*, *Porites napopora*, and *Seriatopora aculeata*). For the two species in the Caribbean currently listed as threatened (*Acropora cervicornis* and *Acropora palmata*), through this final rule we have conducted an updated status review and threats assessment, and determined they still warrant listing as threatened. We also determined that 43 proposed species do not warrant listing as endangered or threatened: two in the Caribbean (*Agaricia lamarcki*, *Dichocoenia stokesii*); and 41 in the Indo-Pacific (*Acanthastrea brevis*, *Acanthastrea hemprichii*, *Acanthastrea ishingakiensis*, *Acanthastrea regularis*, *Acropora aculeus*, *Acropora acuminata*, *Acropora aspera*, *Acropora dendrum*, *Acropora donei*, *Acropora horrida*, *Acropora listeri*, *Acropora microclados*, *Acropora palmerae*, *Acropora paniculata*, *Acropora polystoma*, *Acropora striata*, *Acropora vaughani*, *Acropora verweyi*, *Alveopora allingi*, *Alveopora fenestrata*, *Alveopora verrilliana*, *Anacropora puertogalerae*, *Astreopora cucullata*, *Barabattoia laddi*, *Caulastrea echinulata*, *Euphyllia cristata*, *Euphyllia paraancora*, *Isopora cuneata*, *Millepora tuberosa*, *Montipora angulata*, *Montipora calcarea*, *Montipora caliculata*, *Montipora dilatata/flabellata/turgescens*, *Montipora lobulata*, *Montipora patula/verilli*, *Pachyseris rugosa*, *Pectinia allicornis*, *Physogyra lichtensteini*, *Porites horizontalata*, and *Porites nigrescens*). Three coral species were not

determinable due to taxonomic uncertainty (*Pocillopora danae*, *Pocillopora elegans* (eastern Pacific), *Pocillopora elegans* (Indo-Pacific)).

As described previously in the Risk Analyses section, in this final rule we took a more holistic approach in response to public comments and reconsidered these coral species' demographic and distribution traits that buffer or moderate exposure to threats, and the resulting capacity to respond to changing conditions into the foreseeable future. This approach led to changes in listing status from the proposed rule for 58 of the 68 species while determinations for 10 species remained the same. While in some cases, a warranted species possesses one particularly compelling characteristic that increases its vulnerability to extinction (e.g., a small effective population size, a depth restriction to shallow waters, or a highly constrained geographic range), no one factor in isolation led to a species being warranted for listing and the final determinations are all based on the suite of demographic, spatial, and susceptibility components that influence the species' vulnerability to extinction in the face of continuing threats over the foreseeable future.

Similarly, many of the not warranted species either lack one compelling characteristic that increases vulnerability to extinction or possess one or more compelling characteristics that reduce vulnerability to extinction (e.g., a vast geographic distribution, low susceptibility to high importance threats, a depth range extending into deeper waters, or a large absolute abundance estimate), but no one factor in isolation led to a species being not warranted for listing and the final determinations are all based on the suite of demographic, spatial, and susceptibility components that influence the species' vulnerability to extinction, in the face of continuing threats over the foreseeable future.

#### Effects of Listing

Conservation measures provided for species listed as endangered or threatened under the ESA may include recovery plans (16 U.S.C. 1553(f)), critical habitat designations, Federal agency consultation requirements (16 U.S.C. 1536), and prohibitions on taking (16 U.S.C. 1538). Recognition of the species' plight through listing promotes conservation actions by Federal and state agencies, private groups, and individuals, as well as the international community. For listed species, a recovery program could be implemented, and critical habitat will

be designated to the maximum extent prudent and determinable, for species that occur in U.S. jurisdiction. Protective regulations for threatened corals may be developed for the conservation of the species. Federal, state and private sector cooperation and participation will be necessary to effectively and efficiently conserve the listed coral species and the ecosystems upon which they depend.

#### Identifying Section 7 Consultation Requirements

Section 7(a)(2) of the ESA and NMFS/FWS regulations require Federal agencies to consult with us on any actions they authorize, fund, or carry out if those actions may affect the listed species or designated critical habitat. Based on currently available information, examples of Federal actions that may affect the 22 coral species listed as threatened include, but are not limited to: Energy projects, discharge of pollution from point sources, non-point source pollution, dredging, pile-driving, setting of water quality standards, vessel traffic, aquaculture facilities, military activities, and fisheries management practices.

#### Critical Habitat

Critical habitat is defined in section 3 of the ESA as: "(i) the specific areas within the geographical area occupied by the species, at the time it is listed in accordance with the provisions of section 1533 of this title, on which are found those physical or biological features (I) essential to the conservation of the species and (II) which may require special management considerations or protection; and (ii) specific areas outside the geographical area occupied by the species at the time it is listed in accordance with the provisions of 1533 of this title, upon a determination by the Secretary that such areas are essential for the conservation of the species" (16 U.S.C. 1532(5)(A)). "Conservation" means the use of all methods and procedures needed to bring the species to the point at which listing under the ESA is no longer necessary (16 U.S.C. 1532(3)). Section 4(a)(3)(A) of the ESA requires that, to the maximum extent prudent and determinable, critical habitat be designated concurrently with the final listing of a species (16 U.S.C. 1533(a)(3)(A)(i)). Further, ESA implementing regulations at 50 CFR 424.12(h) specify that critical habitat shall not be designated within foreign countries or in other areas outside of U.S. jurisdiction.

The existing designated critical habitat for *Acropora palmata* and *A.*

*cervicornis* in the Caribbean (50 CFR 226.216) remains effective with this final rule. The designation of critical habitat is not determinable for any of the newly listed corals at this time due to the extremely complex biological and physical requirements of the species. Although we have gathered information through the status review and public comment processes on the habitats occupied by these species, we currently do not have enough information to determine which of features within those habitats are essential to the conservation of any of the listed corals and may require special management considerations or protection. We will continue to gather and review other ongoing studies on the habitat use and requirements of the newly listed corals to attempt to identify these features. Additionally, we need more time to gather the information needed to perform the required analyses of the impacts of the designation. Designations of critical habitat must be based on the best scientific data available and must take into consideration the economic, national security, and other relevant impacts of specifying any particular area as critical habitat. To the maximum extent prudent and determinable, we will publish proposed designations of critical habitat for the newly listed corals in a separate rule or rules. Once critical habitat is designated (only in U.S. jurisdictions), section 7 of the ESA requires Federal agencies to ensure that they do not fund, authorize, or carry out any actions that are likely to destroy or adversely modify that habitat. This requirement is in addition to the section 7 requirement that Federal agencies ensure that their actions are not likely to jeopardize the continued existence of listed species.

#### ESA Section 9 Take Prohibitions

ESA section 9(a) take prohibitions (16 U.S.C. 1538(a)(1)(B)) apply to all species listed as endangered. These section 9(a) prohibitions include prohibitions against importing, exporting, engaging in foreign or interstate commerce, or "taking" of the species. "Take" is defined under the ESA as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct." These prohibitions apply to all persons subject to the jurisdiction of the United States, including in the United States, its territorial sea, or on the high seas. In the case of threatened species, section 9 prohibitions do not automatically apply. Section 4(d) of the ESA directs the Secretary to issue regulations she considers necessary and advisable for the conservation of the species, which

may include applying some or all of the section 9 prohibitions to these species. Therefore, pursuant to ESA section 4(d), subsequent to this rulemaking we will evaluate whether there are protective regulations necessary and advisable for the conservation of any of the 20 species newly-listed as threatened in this final rule, including application of some or all of the take prohibitions. The existing 4(d) rule for *Acropora palmata* and *A. cervicornis* (50 CFR 223.208) will remain in effect for these threatened species.

#### Policies on Role of Peer Review

In December 2004, the Office of Management and Budget (OMB) issued a Final Information Quality Bulletin for Peer Review establishing minimum peer review standards, a transparent process for public disclosure of peer review planning, and opportunities for public participation. The OMB Bulletin, implemented under the Information Quality Act (Public Law 106-554) is intended to enhance the quality and credibility of the Federal government's scientific information, and applies to influential or highly influential scientific information disseminated on or after June 16, 2005. To satisfy our requirements under the OMB Bulletin, the BRT obtained independent peer review of the draft Status Review Report, and NMFS obtained independent peer review of the draft Management Report. Independent specialists were selected from the academic and scientific community, Federal and state agencies, and/or the private sector for this review. All peer reviewer comments were addressed prior to dissemination of the final SRR and Management Report.

We determined that the peer review conducted pursuant to the OMB Bulletin also satisfied the requirements of the Services' 1994 policy for peer review of scientific data included in listing decisions (59 FR 34270).

#### Solicitation of Information

We are soliciting information on features and areas that may support designations of critical habitat for the 20 newly listed coral species. Information provided should identify the physical and biological features essential to the conservation of the species and areas that contain these features for the coral species proposed to be listed. Areas outside the occupied geographical area should also be identified if such areas themselves are essential to the conservation of the species. Essential features may include, but are not limited to, features specific to individual species' ranges, habitats and

life history characteristics within the following general categories of habitat features: (1) Space for individual growth and for normal behavior; (2) food, water, air, light, minerals, or other nutritional or physiological requirements; (3) cover or shelter; (4) sites for reproduction and development of offspring; and (5) habitats that are protected from disturbance or are representative of the historical, geographical, and ecological distributions of the species (50 CFR 424.12(b)). ESA implementing regulations at 50 CFR 424.12(h) specify that critical habitat shall not be designated within foreign countries or in other areas outside of U.S. jurisdiction. Therefore, we request information only on potential areas of critical habitat within waters in U.S. jurisdiction.

For features and areas potentially qualifying as critical habitat, we also request information describing: (1) Activities or other threats to the essential features or activities that could be affected by designating them as critical habitat, and (2) the positive and negative economic, national security and other relevant impacts, including benefits to the recovery of the species, likely to result if these areas are designated as critical habitat.

#### Classification

##### *National Environmental Policy Act*

The 1982 amendments to the ESA, in section 4(b)(1)(A), restrict the information that may be considered when assessing species for listing. Based on this limitation of criteria for a listing decision and NOAA Administrative Order 216-6 (Environmental Review Procedures for Implementing the National Environmental Policy Act), we have concluded that ESA listing actions are not subject to requirements of the National Environmental Policy Act.

##### *Executive Order 12866, Regulatory Flexibility Act, and Paperwork Reduction Act*

As noted in the Conference Report on the 1982 amendments to the ESA, economic impacts cannot be considered when assessing the status of a species. Therefore, the economic analysis requirements of the Regulatory Flexibility Act are not applicable to listing actions.

In addition, this final rule is exempt from review under E.O. 12866.

This final determination does not contain a collection of information requirement for the purposes of the Paperwork Reduction Act.

*Executive Order 13132, Federalism*

In accordance with E.O. 13132, agencies are required to take into account any federalism impacts of regulations under development. This Executive Order includes specific consultation directives for situations where a regulation will preempt state law, or impose substantial direct compliance costs on state and local governments (unless required by statute). Neither of those circumstances is applicable to this final listing determination. In keeping with the intent of the Administration and Congress to provide continuing and meaningful dialogue on issues of mutual state and Federal interest, the proposed rule was provided to the relevant agencies in each state in which the subject species occurs, and these agencies were invited to comment. Their comments were addressed with other comments in the Summary of Comments Received section.

*Executive Order 12898, Environmental Justice*

Executive Order 12898 requires that Federal actions address environmental justice in the decision-making process. In particular, the environmental effects of the actions should not have a disproportionate effect on minority and low-income communities. This final rule is not expected to have a disproportionately high effect on minority populations or low-income populations.

**List of Subjects in 50 CFR Part 223**

Endangered and threatened species; Exports; Imports; Transportation.

Dated: August 26, 2014.

**Eileen Sobeck,**  
Assistant Administrator for Fisheries,  
National Marine Fisheries Service.

For the reasons set out in the preamble, 50 CFR part 223 is amended as follows:

**PART 223—THREATENED MARINE AND ANADROMOUS SPECIES**

■ 1. The authority citation for part 223 continues to read as follows:

**Authority:** 16 U.S.C. 1531–1543; subpart B, § 223.201–202 also issued under 16 U.S.C. 1361 *et seq.*; 16 U.S.C. 5503(d) for § 223.206(d)(9).

■ 2. In § 223.102, in the table, amend paragraph (e) by removing the two existing entries under the “Corals” subheading and adding the following 22 entries to read as follows:

**§ 223.102 Enumeration of threatened marine and anadromous species.**

48 CFR Parts 515, 538, and 552

General Services Administration Acquisition Regulation; Federal Supply Schedule Contracting (Administrative Changes); Proposed Rule

**GENERAL SERVICES ADMINISTRATION**

**48 CFR Parts 515, 538, and 552**

[GSAR Case 2013–G502; Docket 2014–0009; Sequence 1]

RIN 3090–AJ41

**General Services Administration Acquisition Regulation; Federal Supply Schedule Contracting (Administrative Changes)**

**AGENCY:** Office of Acquisition Policy, General Services Administration.

**ACTION:** Proposed rule with request for comments.

**SUMMARY:** The General Services Administration (GSA) is proposing to amend the General Services Administration Acquisition Regulation (GSAR) to clarify and update the contracting by negotiation GSAR section and incorporate existing Federal Supply Schedule Contracting policies and procedures, and corresponding provisions and clauses.

**DATES:** Interested parties should submit written comments to the Regulatory Secretariat on or before November 10, 2014 to be considered in the formulation of a final rule.

**ADDRESSES:** Submit comments identified by GSAR Case 2013–G502, Federal Supply Schedule Contracting (Administrative Changes), by any of the following methods:

- *Regulations.gov:* <http://www.regulations.gov>.

Submit comments by searching for “GSAR Case 2013–G502”. Select the link “Comment Now” and follow the instructions provided at the “You are commenting on” screen. Please include your name, company name (if any), and “GSAR Case 2013–G502”, on your attached document.

- *Fax:* 202–501–4067.
- *Mail:* U.S. General Services Administration, Regulatory Secretariat Division (MVCB), 1800 F Street, NW., 2nd Floor, ATTN: Hada Flowers, Washington, DC 20405–0001.

*Instructions:* Please submit comments only and cite GSAR Case 2013–G502 in all correspondence related to this case. All comments received will be posted without change to <http://www.regulations.gov>, including any personal and/or business confidential information provided.

**SUPPLEMENTARY INFORMATION:**

**I. Background**

GSA is proposing to amend the General Services Administration Acquisition Regulation (GSAR) to update the text addressing GSAR part 515, Contracting by Negotiation, GSAR part 538, Federal Supply Schedule Contracting, and corresponding provisions and clauses in GSAR part

552, Solicitation Provisions and Contract Clauses.

GSAR Part 538 will be amended to include MAS policies contained in FAS Acquisition Letters (ALs) and Instructional Letters (ILs). Bringing these policies into the GSAM will allow for greater transparency and an opportunity for the public to comment on these longstanding procedures.

The proposed changes included in this rulemaking are as follows:

1. GSAR 538.273 is restructured to be more consistent with the formation of Federal Supply Schedule (FSS) solicitations and contracts. The previous structure of GSAR 538.273 was based upon whether the FSS was single-award or multiple-award. A more practical structure outlines where each provision or clause shall be located in FSS solicitations and contracts (e.g., as an addendum to FAR clause 52.212–1 or 52.212–4).

2. Thirty five (35) new FSS-specific clauses and provisions, previously implemented through internal FAS policy and currently in FSS solicitations and contracts will be incorporated into GSAR parts 538 and 552. Bringing these clauses and provisions into the GSAM allows for greater transparency, and consolidates all regulations into one area, while updating administrative information to ensure currency and consistency within the FSS program. This also allows the public an opportunity to comment on these longstanding procedures. The thirty-five (35) new clauses, prescriptions, and a brief description are as follows:

New #	New name	Prescription	Description/Purpose of the provision/ Clause
552.238–82 .....	Delivery Schedule .....	Use only in FSS solicitations and contracts for supplies.	This clause provides to the Offeror the requirement to address normal commercial delivery times in its offer.
552.238–83 .....	GSA Advantage! .....	Use in all FSS solicitations and contracts except the Department of Veterans Affairs Federal Supply Schedules.	This clause outlines to the Contractor that it must participate in the GSA Advantage!® online shopping service. This clause is not applicable to the Department of Veterans Affairs.
552.238–84 .....	Cover Page for Worldwide Federal Supply Schedules.	Use in all FSS solicitations. Use Alternate I for single award Federal Supply Schedules.	This provision notifies the Offeror of the industry and types of products/services being solicited.
552.238–85 .....	Significant Changes .....	Use in all supply and service solicitation refreshes containing revisions since the previous posting to the Government’s point of entry.	This provision outlines to Offerors the most recent solicitation revisions since its previous posting to the Government’s point of entry.
552.238–86 .....	Notice of Total Small Business Set-Aside.	Use in supply and service solicitations containing special item numbers (SINs) that are set aside for small business.	This provision notifies small business Offerors which Special Item Numbers (SINs) are set aside.
552.238–87 .....	Information Collection Requirements .....	Use in all FSS solicitations.	This provision informs Offerors that only required regulations are contained in the solicitation.

New #	New name	Prescription	Description/Purpose of the provision/ Clause
552.238-88 .....	Notice: Requests for Explanation or Information and Hours of Operation.	Use in all FSS solicitations.	This provision contains the contact information to address questions regarding the solicitation and the hours of operation.
552.238-90 .....	Introduction of New Supplies/Services (INSS).	Use only in FSS solicitations allowing the introduction of new supplies/services. Note: GSA Form 1649, Notification of Federal Supply Schedule Improvement, may be required if revising a Special Item Number (SIN).	This provision notifies offerors of the method to propose new services or supplies not covered by the Schedule.
552.238-91 .....	Authorized Negotiators .....	Use in all FSS solicitations.	This provision ensures only authorized personnel represent the contractor.
552.238-93 .....	Use of Non-Government Employees to Review Offers.	Use only in FSS solicitations when non-government employees may be utilized to review solicitation responses.	This provision provides notification to Offerors that non-government employees may be utilized to review their solicitation response.
552.238-94 .....	Examination of Records by GSA (Federal Supply Schedule).	Use in all FSS solicitations and contracts.	This clause notifies the Offeror that GSA shall have access to and the right to examine any books, documents, papers, and records involving transactions related to its FSS contract.
552.238-99 .....	Deliveries to the U.S. Postal Service ....	Use only in FSS solicitations and contracts for mailable articles when delivery to a U.S. Postal Service (USPS) facility is contemplated.	This clause provides requirements for the delivery of mailable articles delivered direct to a USPS facility. The clause ensures the use of the USPS to reduce unnecessary costs of shipping.
552.238-100 .....	Characteristics of Electric Current .....	Use only in FSS solicitations and contracts when the supply of equipment which uses electrical current is contemplated.	This clause requires the contractor to provide equipment with electrical currents suitable for the location in which the equipment is to be used, as specified on the order.
552.238-101 .....	Marking and Documentation Requirements for Shipping.	Use only in FSS solicitations and contracts for supplies when the need for outlining the minimum information and documentation required for shipping is contemplated.	This clause defines the responsibility of ordering activities and contractors for the marking and documentation of shipping information.
552.238-102 .....	Inspection .....	Use only in FSS solicitations and contracts when all items are to be inspected at a destination by a Government representative. Use Alternate I when it is anticipated that additional terms and conditions regarding responsibility for rejected supplies and additional costs for inspection and testing are required.	This clause informs contractors that items are to be inspected at a destination by an authorized Government representative. Alternate I includes terms and conditions regarding responsibility for rejected supplies and additional costs for inspection and testing.
552.238-103 .....	Vendor Managed Inventory (VMI) Program (MAS).	Use only in FSS solicitations and contracts for supplies when a VMI Program is contemplated.	This clause allows Contractors that commercially provide a VMI type system to enter into similar partnerships with customers under a Blanket Purchase Agreements.
552.238-104 .....	Order Acknowledgement .....	Use only in FSS solicitations and contracts for supplies.	This clause requires Contractors to acknowledge orders which state "Order Acknowledgement Required" within 10 calendar days after receipt to the ordering activity placing the order and contain information pertinent to the order, including the anticipated delivery date.
552.238-105 .....	Urgent Requirements .....	Use only in FSS solicitations and contracts for supplies.	This clause assists with ordering activities to receive accelerated delivery when the FSS contract delivery period does not meet the bona fide urgent delivery requirements of an ordering activity.
552.238-106 .....	Post-Award Samples .....	Use only in FSS solicitations and contracts for the acquisition of carpet.	This clause instructs the Contractor of submission requirements.

New #	New name	Prescription	Description/Purpose of the provision/ Clause
552.238-107 .....	Restriction on the Acceptance of Orders	Use only in FSS solicitations and contracts for electrostatic copying equipment, supplies (toner, developer, fuser oil) for such equipment, repair or replacement parts for such equipment, and maintenance or repair service for such equipment.	This clause sets restrictions on orders and deliveries in connection with the United States Navy and the Military Sealift Command.
552.238-108 .....	Separate Charge for Performance Oriented Packaging (POP).	Use only in FSS solicitations and contracts for items defined as hazardous under Federal Standard No. 313.	This clause ensures both parties, contractors and ordering activities, are aware of a separate charge for preservation, packaging, packing and marking and labeling of domestic and overseas HAZMAT SURFACE SHIPMENTS.
552.238-109 .....	Additional Service Charge for Delivery Within Consignee's Premises.	Use only in FSS solicitations and contracts for supplies when allowing offerors to propose separate charges for deliveries within the consignee's premises.	This clause ensures both parties, contractors and ordering activities, are aware of a separate charges for deliveries within the consignee's premises.
552.238-110 .....	Shipping Points .....	Use only in FSS solicitations and contracts for supplies when F.O.B. Origin shipments are contemplated.	This clause instructs the Offeror to provide shipping information, inclusive of carrier and address, for F.O.B. Origin shipments.
552.238-111 .....	Contact for Contract Administration .....	Use in all FSS solicitations and contracts.	This clause instructs Offerors to provide points of contact for domestic and/or overseas contact information for contract administration.
552.238-112 .....	Clauses for Overseas Coverage .....	Use only in FSS solicitations and contracts when overseas acquisition is contemplated. The following clauses and provisions shall also be inserted in full text, when applicable.	This clause ensures all applicable overseas clauses are included in the solicitation and contract.
552.238-113 .....	Parts and Service .....	Use in all FSS solicitations and contracts.	This clause is used to ensure that the parts and services (including the performance of warranty or guarantee service) submitted by Offerors (dealers/distributors) is good for the entire contract period.
552.238-114 .....	Delivery Prices Overseas .....	Use only in FSS solicitations and contracts when overseas acquisition is contemplated.	This clause is for use for F.O.B. Destination in overseas deliveries to ensure that all parties are aware of delivery terms.
552.238-115 .....	Transshipments .....	Use in all FSS solicitations and contracts.	This clause states the terms and conditions for transshipments, and provides information to contractors with the necessary Department of Defense forms.
552.238-116 .....	Foreign Taxes and Duties .....	Use only in FSS solicitations and contracts when overseas acquisition is contemplated.	This clause delineates which fees, taxes and other foreign governmental costs are exempt/non-exempt by the U.S. Government.
552.238-117 .....	English Language and U.S. Dollar Requirements.	Use in all FSS solicitations and contracts.	This clause is used to instruct Contractors that all documents shall be produced in the English language, including, but not limited to, price lists and catalogs.
552.238-118 .....	Delivery Prices .....	Use in all FSS solicitations and contracts.	This clause ensures all parties are aware of the delivery terms of the contract.
552.238-119 .....	Federal Excise Tax .....	Use only in FSS solicitations and contracts for tire and tube acquisitions.	This clause instructs ordering activities on the procedures for invoicing the Federal Excise Tax, and requires contractors to quote this tax separately.
552.238-120 .....	Guarantee .....	Use only in FSS solicitations and contracts for major appliances.	This clause outlines the guarantee afforded to the Government for a period of one year from the date of delivery.
552.238-121 .....	Electronic Commerce .....	Use in all FSS solicitations and contracts except the Department of Veterans Affairs Federal Supply Schedules.	This clause outlines the use of electronic commerce/data interchange to conduct contract processes and procedures.

New #	New name	Prescription	Description/Purpose of the provision/ Clause
552.238-122 .....	Imprest Funds (Petty Cash) .....	Use in all FSS solicitations and contracts.	This clause outlines to the Contractor that it agrees to accept cash payment for purchases under the terms of the contract in accordance with FAR 13.305.
552.238-123 .....	Dissemination of Information by Contractor.	Use in all FSS solicitations and contracts.	This clause provides to the Contractor the responsibility of distributing Authorized Federal Supply Schedule Price Lists to all authorized sales outlets.
552.238-124 .....	Deliveries Beyond the Contractual Period—Placing of Orders.	Use only in FSS solicitations and contracts for supplies.	This clause allows orders to be processed if they were received prior to the expiration of the contract.
552.238-125 .....	Interpretation of Contract Requirements	Use in all FSS solicitations and contracts.	This indicates that only written clarifications regarding interpretation of contract clauses may only be made by the Contracting Officer or his/her designated representative.
552.238-126 .....	Export Traffic Release (Supplies) .....	Use in FSS solicitations and contracts for supplies, except vehicles.	This clause informs contractors of the requirements for exporting items under the contract.
552.238-127 .....	Export Traffic Release (Vehicles) .....	Use only in FSS solicitations and contracts for vehicles.	This clause informs contractors of the requirements for exporting vehicles under the contract.
552.238-128 .....	Carload Shipments .....	Use only in FSS solicitations and contracts for vehicles.	This clause provides the requirements to ship cars by rail.
552.238-129 .....	Spare Parts Kit .....	Use only in FSS solicitations and contracts for items requiring spare part kits.	This clause ensures requirements for spare part kits are understood by all parties.
552.238-130 .....	Authentication Supplies and Services ...	Use in Federal Supply Schedule 70 solicitations only, and only contracts awarded Special Item Numbers (SINs) associated with the Homeland Security Presidential Directive 12 (HSPD-12).	This clause outlines requirements for the Homeland Security Presidential Directive 12 (HSPD-12).
552.238-131 .....	Commercial Satellite Communication (COMSATCOM) Services.	Use only in FSS solicitations and contracts for COMSATCOM services.	This clause provides minimum requirements for COMSATCOM services.
552.238-132 .....	Environmental Protection Agency Registration Requirement.	Use only in FSS solicitations and contracts for supplies when items may require registration with the Environmental Protection Agency.	This clause ensures items in FSC Group 68 items (insecticides, etc.) are properly registered with EPA.

3. Prescriptions for the following seven (7) existing clauses are updated to reflect current practices:

Clause	Name	Prescription	Description/Purpose of the provision/ Clause
552.238-70 .....	Identification of Electronic Office Equipment Providing Accessibility for the Handicapped.	Use only in FSS solicitations for electronic office equipment.	This clause instructs the Offeror to identify accessible electronic office equipment included in its proposal.
552.238-71 .....	Submission and Distribution of Authorized Federal Supply Schedule (FSS) Price Lists.	Use in all FSS solicitations and contracts.	This clause instructs the Offeror on how and when to submit and distribute its authorized FSS pricelists.
552.238-72 .....	Identification of Products that have Environmental Attributes.	Use only in FSS solicitations and contracts that contemplate items with environmental attributes.	This provision instructs the Offeror to identify products included in its proposal that have environmental attributes.
552.238-73 .....	Cancellation .....	Use in all FSS solicitations and contracts.	This clause provides instructions to the Offeror on cancelling its FSS contracts.
552.238-74 .....	Industrial Funding Fee and Sales Reporting.	Use in all FSS solicitations and contracts.	This clause provides instructions to the Offeror on submitting the IFF.
552.238-75 .....	Price Reductions .....	Use in all FSS solicitations and contracts. Use Alternate I in solicitations and contracts for— (i) Federal Supply Schedule 70;	This clause outlines the evaluation methodology triggering the PRC.

Clause	Name	Prescription	Description/Purpose of the provision/ Clause
552.238–81 .....	Modifications (Federal Supply Schedules).	(ii) The Consolidated Schedule containing information technology Special Item Numbers; (iii) Federal Supply Schedule 84; and (iv) Federal Supply Schedules for recovery purchasing (see 538.7102). Use in all FSS solicitations and contracts. (i) Use Alternate I for Federal Supply Schedules that only accept eMod.	This clause provides to the Offeror instructions on adding and deleting, special item numbers, products and services from its contract.

4. Six (6) FSS-specific provisions and clauses that were removed from the GSAR as part of a previous General Services Administration Acquisition Manual (GSAM) rewrite are reinstated and given new clause numbers. Specifically, GSAR Case 2006–G507,

“*Rewrite of GSAR Part 538, Federal Supply Schedule Contracting*,” was published in the **Federal Register** at 74 FR 4596 on January 26, 2009 and removed the clauses. Since then, the clauses have been and are retained by GSA Acquisition Letter (AL) V–09–10

(and its supplements). The clauses and provisions contained therein are proposed to be reinstated into GSAR Parts 538 and 552 in order to ensure consistency and transparency and to provide the public an opportunity to comment.

THE REINSTATED CLAUSES ARE AS FOLLOWS:

Clause title	New GSAR location	New number	Previous number (s)
Contractor’s Remittance (Payment) Address .....	538.273(b)(2)	552.238–89	552.232–82
Evaluation—Commercial Items (Federal Supply Schedule) .....	538.273(c)(1)	552.238–92	552.212–73
Discount for Prompt Payment (Federal Supply Schedule) .....	538.273(d)(10)	552.238–95	552.232–8
Contractor’s Billing Responsibilities .....	538.273(d)(11)	552.238–96	552.232–83
Payment by Credit Card .....	538.273(d)(12)	552.238–97	552.232–79
Warranty (Federal Supply Schedule) .....	538.273(d)(13)	552.238–98	552.246–73

5. The GSAR clause at 552.215–71, Examination of Records by GSA (Multiple Award Schedule), is relocated to GSAR part 538. As part of the GSAR rewrite, GSA is relocating the instructions for using all clauses and provisions dealing with the FSS Program to GSAM part 538. Bringing these instructions into one area ensures currency and consistency within the FSS program. This provides better guidance to FSS contracting officers when developing FSS solicitations and contracts.

6. Typographical errors are corrected and minor administrative changes are made to GSAR parts 538 and 552 (e.g., renumbers existing provisions and clauses, changes “MAS” to “FSS” to be more consistent with the FAR).

**II. Executive Orders 12866 and 13563**

Executive Orders (E.O.s) 12866 and 13563 direct agencies to assess all costs and benefits of available regulatory alternatives and, if regulation is necessary, to select regulatory approaches that maximize net benefits (including potential economic, environmental, public health and safety effects, distributive impacts, and equity). E.O. 13563 emphasizes the

importance of quantifying both costs and benefits, of reducing costs, of harmonizing rules, and of promoting flexibility. This is not a significant regulatory action and, therefore, was not subject to review under section 6(b) of E.O. 12866, Regulatory Planning and Review, dated September 30, 1993. This rule is not a major rule under 5 U.S.C. 804.

**III. Regulatory Flexibility Act**

GSA does not expect this proposed rule to have a significant economic impact on a substantial number of small entities within the meaning of the Regulatory Flexibility Act 5 U.S.C. 601, *et seq.*, because the proposed rule will incorporate a number of provisions and clauses that are currently in use in FSS solicitations and contracts and most contractors are familiar with and are currently complying with these practices. However, since this is the first time these proposed changes and existing policies and procedures that impact the public are being published, an Initial Regulatory Flexibility Analysis (IRFA) has been prepared. The Secretariat has submitted a copy of the IRFA to the Chief Counsel for Advocacy of the Small Business Administration. A

copy of the IRFA may be obtained from the Regulatory Secretariat. GSA will consider comments from small entities concerning the affected GSAR parts in accordance with 5 U.S.C. 610. Comments must be submitted separately and shall cite 5 U.S.C. 601, *et seq.* (GSAR Case 2013–G502), in correspondence. The analysis is summarized as follows:

This IRFA has been prepared consistent with the criteria of 5 U.S.C. 604.

There are approximately 20,500 FSS contracts that are affected by this proposed change. Of these, approximately eighty percent (16,400) of FSS contracts are held by small businesses. The proposed rule is unlikely to affect small businesses awarded GSA FSS contracts as it implements a number of provisions and clauses currently in use in FSS solicitations and contracts, yet not vetted via public comment. The information collected is used by FAS to evaluate vendors’ offers, ordering activities when placing orders against the contract, and other FSS vendors to conduct market research when submitting proposals. Therefore, this rule does not pose any new projected reporting, recordkeeping, or additional compliance requirements. Bringing these regulations into the GSAM consolidates all regulations into one area, allowing for any future changes to receive public comment.

There are a total of 31 Schedules, with 14 possessing an array of Special Item Numbers (SINs) set-aside for small businesses. Overall, small businesses have benefited from GSA providing access to the Federal marketplace via the Pre-award phase (Pathway to Success), the Post-award phase (New Contractor Orientation), and Contractor Assistance Visits (CAVs). FSS contracts are negotiated as volume purchase agreements, with generally very favorable pricing. The ability of small businesses to receive awards under the FSS Program has enabled them to grow in the Federal marketplace as well as realize significant cost savings.

#### IV. Paperwork Reduction Act

The Paperwork Reduction Act (44 U.S.C. chapter 35) applies because the proposed rule contains information collection requirements. Accordingly, the Regulatory Secretariat has submitted a request for approval of a new information collection requirement concerning OMB Control Number 3090-0303; Administrative Changes to the Office of Management and Budget under 44 U.S.C. 3501, *et seq.*

##### A. Annual Reporting Burden

The information collected is used by FAS to evaluate vendors' offers, ordering activities when placing orders against the contract, and other FSS vendors to conduct market research when submitting proposals.

Total public reporting burden for this collection of information is estimated to average 2,988 total hours, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Annual reporting burdens include the estimated respondents with 1 submission per respondent multiplied by preparation hours per response to get the total response burden hours. The estimated burden hours to the public for the below clauses are as follows:

The new provision at GSAR 552.238-89, Contractor Remittance (Payment) Address, requires the offeror to indicate the payment address to which checks shall be mailed for payment of invoices and to identify participating dealers and provide their addresses for receiving orders and payments on behalf of the contractor.

*Respondents:* 20,500.

*Responses per respondent:* 1.

*Total annual responses:* 20,500.

*Preparation hours per response:* 0.0333.

*Total response burden hours:* 683.

The new provision at GSAR 552.238-91, Authorized Negotiators, requires the offeror to outline its point-of-contact information for negotiations.

*Respondents:* 20,500.

*Responses per respondent:* 1.

*Total annual responses:* 20,500.

*Preparation hours per response:* 0.0333.

*Total response burden hours:* 683.

The new clause at GSAR 552.238-95, Discounts for Prompt Payment (Federal Supply Schedules), requires the offeror to provide the Government a discount for early payment, if applicable.

*Respondents:* 20,500.

*Responses per respondent:* 1.

*Total annual responses:* 20,500.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 342.

The new clause at GSAR 552.238-108, Separate Charge for Performance Oriented Packaging, requires the offeror to list any separate charge for preservation, packaging, packing and marking, and labeling of domestic and overseas HAZMAT surface shipments.

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at GSAR 552.238-109, Additional Service Charge for Delivery within Consignee's Premises, requires the offeror to list any separate cost for shipping when the delivery is within the consignee's premises (inclusive of items that are comparable in size and weight).

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at GSAR 552.238-110, Shipping Points, requires the offeror to provide shipping information, inclusive of carrier and address, for F.O.B. Origin shipments.

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at 552.238-111, Contact for Contract Administration, requires the offeror to provide points of contact for domestic and/or overseas contact information.

*Respondents:* 20,500.

*Responses per respondent:* 1.

*Total annual responses:* 20,500.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 342.

The new clause at 552.238-113, Parts and Service, requires the offeror to include in the price list, the names and

addresses of all supply and service points maintained in the geographic area in which the offeror will perform, whether or not a complete stock of repair parts for items offered is carried at that point, and whether or not mechanical service is available.

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at 552.238-114, Delivery Prices Overseas, requires the offeror to identify the intended geographic area(s)/countries/zones which are to be covered.

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at 552.238-118, Delivery Prices, requires the offeror to identify the intended geographic area(s)/countries/zones that are to be covered.

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at 552.238-134, Environmental Protection Agency Registration Requirement, requires the offeror to list the manufacturer's and/or distributor's name and EPA Registration Number for each item requiring registration with the EPA.

*Respondents:* 8,000.

*Responses per respondent:* 1.

*Total annual responses:* 8,000.

*Preparation hours per response:* 0.0167.

*Total response burden hours:* 134.

The new clause at GSAR 552.238-96, Contractor's Billing Responsibilities, contains a recordkeeping requirement that is subject to the Paperwork Reduction Act (44 U.S.C. 3501, *et seq.*).

The clause provides for the contractor to require all dealers participating in the performance of the contract to agree to maintain certain records on sales made under the contract on behalf of the contractor. However, it does not add burden to what is already estimated for the existing GSAR clause at 552.238-74, Industrial Funding Fee and Sales Reporting by a previous information collection (see OMB Control Number 3090-0121; Industrial Funding Fee and Sales Reporting).

##### B. Requests for Comments Regarding Paperwork Burden

Submit comments, including suggestions for reducing this burden,

not later than November 10, 2014 to: GSA Desk Officer, OMB, Room 10102, NEOB, Washington, DC 20503, and a copy to the General Services Administration, Regulatory Secretariat Division (MVCB), ATTN: Ms. Flowers, 1800 F Street NW., 2nd Floor, Washington, DC 20405.

Public comments are particularly invited on: whether this collection of information is necessary for the proper performance of functions of the FAR, and will have practical utility; whether our estimate of the public burden of this collection of information is accurate, and based on valid assumptions and methodology; ways to enhance the quality, utility, and clarity of the information to be collected; and ways in which we can minimize the burden of the collection of information on those who are to respond, through the use of appropriate technological collection techniques or other forms of information technology.

Requesters may obtain a copy of the supporting statement from the General Services Administration, Regulatory Secretariat (MVCB), ATTN: Ms. Flowers, 1800 F Street NW., 2nd Floor, Washington, DC 20405.

Please cite OMB Control Number 9000-0303, (GSAR) Administrative Changes; GSAR Case 2013-G502, in all correspondence.

#### List of Subjects in 48 CFR Parts 515, 538, and 552

Government procurement.

Dated: August 20, 2014.

Jeffrey A. Koses,

Senior Procurement Executive, Office of Acquisition Policy, Office of Government-wide Policy.

Therefore, GSA proposes to amend 48 CFR parts 515, 538, and 552 as set forth below:

#### PART 515—CONTRACTING BY NEGOTIATION

■ 1. The authority citation for 48 CFR part 515 is revised to read as follows:

**Authority:** 40 U.S.C. 121(c).

#### 515.209–70 [Amended]

■ 2. Amend section 515.209–70 by removing the undesignated center heading “Clause for Multiple Award Schedules” and paragraphs (c) and (d).

#### PART 538—FEDERAL SUPPLY SCHEDULE CONTRACTING

■ 3. The authority citation for 48 CFR part 538 continues to read as follows:

**Authority:** 40 U.S.C. 121(c).

■ 4. Amend section 538.270 by revising the section heading; and removing from

the introductory text of paragraph (c) and paragraph (c)(7) “MAS” and adding “FSS” in their places. The revised heading reads as follows:

#### 538.270 Evaluation of Federal Supply Schedule (FSS) offers.

\* \* \* \* \*

■ 5. Amend section 538.271 by revising the section heading; and removing from paragraphs (a) and (b) “MAS” and adding “FSS” in their places. The revised heading reads as follows:

#### 538.271 FSS contract awards.

\* \* \* \* \*

■ 6. Amend section 538.272 by revising the section heading to read as follows:

#### 538.272 FSS price reductions.

\* \* \* \* \*

■ 7. Revise section 538.273 to read as follows:

#### 538.273 FSS solicitation provisions and contract clauses.

(a) As prescribed in this section, insert the following provisions in the beginning of FSS solicitations:

(1) *552.238–84, Cover Page for Federal Supply Schedules.* Use in all FSS solicitations. Use Alternate I for single award Federal Supply Schedules.

(2) *552.238–85, Significant Changes.* Use in all supply and service solicitation refreshes containing revisions since the previous posting to the Government’s point of entry.

(3) *552.238–86, Notice of Total Small Business Set-Aside.* Use in supply and service solicitations containing one or more special item numbers (SINs) that are set aside for small business.

(4) *552.238–87, Information Collection Requirements.* Use in all FSS solicitations.

(5) *552.238–88, Notice: Requests for Explanation or Information and Hours of Operation.* Use in all FSS solicitations.

(b) As prescribed in this section, insert the following provisions as an addendum to 52.212–1, Instructions to Offerors—Commercial Items:

(1) *552.238–70, Identification of Electronic Office Equipment Providing Accessibility for the Handicapped.* Use only in FSS solicitations for electronic office equipment.

(2) *552.238–89, Contractor’s Remittance (Payment) Address.* Use in all FSS solicitations.

(3) *552.238–90, Introduction of New Supplies/Services (INSS).* Use in all FSS solicitations. Note: GSA Form 1649, Notification of Federal Supply Schedule Improvement, may be required if revising a Special Item Number (SIN).

(4) *552.238–91, Authorized Negotiators.* Use in all FSS solicitations.

(c) As prescribed in this section, insert the following provisions as an addendum to 52.212–2, Evaluation—Commercial Items, when required within the scope of the solicitation:

(1) *552.238–92, Evaluation—Commercial Items (Federal Supply Schedules).* Use in FSS standing solicitations. Use Alternate I for non-standing FSS solicitations.

(2) *552.238–93, Use of Non-Government Employees to Review Offers.* Use only in FSS solicitations when non-government employees may be utilized to review solicitation responses.

(d) As prescribed in this section, insert the following clauses as an addendum to Clause 52.212–4, Contract Terms and Conditions—Commercial Items:

(1) *552.238–71, Submission and Distribution of Authorized Federal Supply Schedule (FSS) Price Lists.* Use in all FSS solicitations and contracts.

(i) Use Alternate I, in solicitations and contracts for—

(A) Federal Supply Schedule 70;

(B) The Consolidated Schedule contracts containing information technology Special Item Numbers;

(C) Federal Supply Schedule 84; and

(D) Federal Supply Schedules for recovery purchasing (see 538.7102), use Alternate I.

(ii) If GSA is not prepared to accept electronic submissions for a particular schedule delete—

(A) The paragraph identifier “(i)” in (b)(1) and the word “and” at the end of paragraph (b)(1)(i); and

(B) Paragraphs (b)(1)(ii) and (b)(3).

(2) *552.238–72, Identification of Products that have Environmental Attributes.* Use only in FSS solicitations and contracts that contemplate items with environmental attributes.

(3) *552.238–73, Cancellation.* Use in all FSS solicitations and contracts.

(4) *552.238–74, Industrial Funding Fee and Sales Reporting.* Use in all FSS solicitations and contracts.

(5) *552.238–75, Price Reductions.* Use in all FSS solicitations and contracts. Use Alternate I in solicitations and contracts for—

(i) Federal Supply Schedule 70;

(ii) The Consolidated Schedule containing information technology Special Item Numbers;

(iii) Federal Supply Schedule 84; and

(iv) Federal Supply Schedules for recovery purchasing (see 538.7102).

(6) *552.238–81, Modifications (Federal Supply Schedules).* Use in all FSS solicitations and contracts. Use Alternate I for Federal Supply Schedules that only accept eMod.

(7) *552.238–82, Delivery Schedule.*

Use only in FSS solicitations and contracts for supplies.

(8) *552.238–83 GSA Advantage!®.* Use in all FSS solicitations and contracts except the Department of Veterans Affairs Federal Supply Schedules.

(9) *552.238–94 Examination of Records by GSA Federal Supply Schedules.* Use in all FSS solicitations and contracts. With the Senior Procurement's Executive approval, the Contracting Officer may modify the clause at 552.238–9 to provide for post-award access to and the right to examine records to verify that the pre-award/modification pricing, sales or other data related to the supplies or services offered under the contract which formed the basis for the award/modification was accurate, current, and complete. The following procedures apply:

(i) Such a modification of the clause must provide for the right of access to expire 2 years after award or modification.

(ii) Before modifying the clause, the Contracting Officer must make a determination that absent such access there is a likelihood of significant harm to the Government and submit it to the Senior Procurement Executive for approval.

(iii) The determinations under paragraph (d)(2) of this section must be made on a schedule-by-schedule basis.

(10) *552.238–95, Discounts for Prompt Payments (Federal Supply Schedules).* Use in all FSS solicitations and contracts.

(11) *552.238–96, Contractor's Billing Responsibilities.* Use in all FSS solicitations and contracts.

(12) *552.238–97, Payment by Credit Card.* Use in all FSS solicitations and contracts.

(13) *552.238–98, Warranty (Federal Supply Schedules).* Use in all FSS solicitations and contracts.

(14) *552.238–99, Deliveries to the U.S. Postal Service.* Use only in FSS solicitations and contracts for mailable articles when delivery to a U.S. Postal Service (USPS) facility is contemplated.

(15) *552.238–100, Characteristics of Electric Current.* Use only in FSS solicitations and contracts when the supply of equipment which uses electrical current is contemplated.

(16) *552.238–101, Marking and Documentation Requirements for Shipping.* Use only in FSS solicitations and contracts for supplies when the need for outlining the minimum information and documentation required for shipping is contemplated.

(17) *552.238–102, Inspection.* Use only in FSS solicitations and contracts when all items are to be inspected at a

destination by a Government representative. Use Alternate I when it is anticipated that additional terms and conditions regarding responsibility for rejected supplies and additional costs for inspection and testing are required.

(18) *552.238–103, Vendor Managed Inventory (VMI) Program.* Use only in FSS solicitations and contracts for supplies when a VMI Program is contemplated.

(19) *552.238–104, Order Acknowledgement.* Use only in FSS solicitations and contracts for supplies.

(20) *552.238–105, Urgent Requirements.* Use only in FSS solicitations and contracts for supplies.

(21) *552.238–106, Post-Award Samples.* Use only in FSS solicitations and contracts for the acquisition of carpet.

(22) *552.238–107, Restriction on the Acceptance of Orders.* Use only in FSS solicitations and contracts for electrostatic copying equipment, supplies (toner, developer, fuser oil) for such equipment, repair or replacement parts for such equipment, and maintenance or repair service for such equipment.

(23) *552.238–108, Separate Charge for Performance Oriented Packaging (POP).* Use only in FSS solicitations and contracts for items defined as hazardous under Federal Standard No. 313.

(24) *552.238–109, Additional Service Charge for Delivery within Consignee's Premises.* Use only in FSS solicitations and contracts for supplies when allowing offerors to propose separate charges for deliveries within the consignee's premises.

(25) *552.238–110, Shipping Points.* Use only in FSS solicitations and contracts for supplies when F.O.B. Origin shipments are contemplated.

(26) *552.238–111, Contact for Contract Administration.* Use in all FSS solicitations and contracts.

(27) *552.238–112, Clauses for Overseas Coverage.* Use only in FSS solicitations and contracts when overseas acquisition is contemplated. The following clauses and provisions shall also be inserted in full text, when applicable.

(i) 52.214–34, Submission of Offers in the English Language.

(ii) 52.214–35, Submission of Offers in U.S. Currency.

(iii) 52.247–34, FOB Destination.

(iv) 52.247–38, FOB Inland Carrier, Country of Exportation.

(v) 52.247–39, FOB Inland Point, Country of Importation.

(vi) 552.238–100, Characteristics of Electric Current.

(vii) 552.238–101, Marking and Documentation Requirements Per Shipment.

(viii) 552.238–113, Parts and Service.

(ix) 552.238–114, Delivery Prices Overseas.

(x) 552.238–115, Transshipments.

(xi) 552.238–116, Foreign Taxes and Duties.

(28) *552.238–117, English Language and U.S. Dollar Requirements.* Use in all FSS solicitations and contracts.

(29) *552.238–118, Delivery Prices.* Use in all FSS solicitations and contracts.

(30) *552.238–119, Federal Excise Tax.* Use only in FSS solicitations and contracts for tire and tube acquisitions.

(31) *552.238–120, Guarantee.* Use only in FSS solicitations and contracts for major appliances.

(32) *552.238–121, Electronic Commerce.* Use in all FSS solicitations and contracts except the Department of Veterans Affairs Federal Supply Schedules.

(33) *552.238–122, Imprest Funds (Petty Cash).* Use in all FSS solicitations and contracts.

(34) *552.238–123, Dissemination of Information by Contractor.* Use in all FSS solicitations and contracts.

(35) *552.238–124, Deliveries Beyond the Contractual Period—Placing of Orders.* Use only in FSS solicitations and contracts for supplies.

(36) *552.238–125, Interpretation of Contract Requirements.* Use in all FSS solicitations and contracts.

(37) *552.238–126, Export Traffic Release (Supplies).* Use in FSS solicitations and contracts for supplies, except vehicles.

(38) *552.238–127, Export Traffic Release (Vehicles).* Use only in FSS solicitations and contracts for vehicles.

(39) *552.238–128, Carload Shipments.* Use only in FSS solicitations and contracts for vehicles.

(40) *552.238–129, Spare Parts Kit.* Use only in FSS solicitations and contracts for items requiring spare part kits.

(41) *552.238–130, Authentication Supplies and Services.* Use in Federal Supply Schedule 70 solicitations only. When the Federal Supply Schedule 70 contract is awarded, use only if the awarded contract includes Special Item Numbers (SINs) associated with the Homeland Security Presidential Directive 12 (HSPD–12).

(42) *552.238–131, Commercial Satellite Communication (COMSATCOM) Services.* Use only in FSS solicitations and contracts for COMSATCOM services.

(43) *552.238–132, Environmental Protection Agency Registration Requirement.* Use only in FSS solicitations and contracts for supplies when items may require registration with the Environmental Protection Agency.

■ 8. Amend section 538.7004 by revising paragraphs (a), (b), and (c) to read as follows:

**538.7004 Solicitation provisions and contract clauses.**

(a) As an addendum to 52.212-4, Contract Terms and Conditions—Commercial Items the contracting officer shall insert the clause at 552.238-77, Definition (Federal Supply Schedules), in solicitations and contracts for:

- (1) Federal Supply Schedule 70;
(2) The Consolidated Schedule containing information technology SINs; and

(3) Federal Supply Schedule 84.

(b) As an addendum to 52.212-4, Contract Terms and Conditions—Commercial Items the contracting officer shall insert the clause at 552.238-78, Scope of Contract (Eligible Ordering Activities), in solicitations and contracts for:

- (1) Federal Supply Schedule 70; and
(2) The Consolidated Schedule containing information technology SINs; and

(3) Federal Supply Schedule 84.

(c) As an addendum to 52.212-4, Contract Terms and Conditions—Commercial Items the contracting officer shall insert the clause at 552.238-79, Use of Federal Supply Schedule Contracts by Certain Entities—Cooperative Purchasing, in solicitations and contracts for:

- (1) Federal Supply Schedule 70;
(2) The Consolidated Schedule containing information technology SINs; and

(3) Federal Supply Schedule 84.

\* \* \* \* \*

■ 9. Amend section 538.7104 by revising paragraphs (a), (b), and (c) to read as follows:

**538.7104 Solicitation provisions and contract clauses.**

(a) As an addendum to 52.212-4, Contract Terms and Conditions—Commercial Items the contracting officer shall insert the clause at 552.238-76, Definition (Federal Supply Schedules)—Recovery Purchasing, in Federal Supply Schedule solicitations and contracts which contain products and services determined by the Secretary of Homeland Security to facilitate recovery from major disasters, terrorism, or nuclear, biological, chemical, or radiological attack.

(b) As an addendum to 52.212-4, Contract Terms and Conditions—Commercial Items the contracting officer shall insert the clause at 552.238-78, Scope of Contract (Eligible Ordering Activities), with Alternate I in

Federal Supply Schedule solicitations and contracts which contain products and services determined by the Secretary of Homeland Security to facilitate recovery from major disasters, terrorism, or nuclear, biological, chemical, or radiological attack.

(c) As an addendum to 52.212-4, Contract Terms and Conditions—Commercial Items the contracting officer shall insert the clause at 552.238-80, Use of Federal Supply Schedule Contracts by Certain Entities—Recovery Purchasing, in Federal Supply Schedule solicitations and contracts which contain products and services determined by the Secretary of Homeland Security that facilitate recovery from major disasters, terrorism, or nuclear, biological, chemical, or radiological attack.

\* \* \* \* \*

**PART 552—SOLICITATION PROVISIONS AND CONTRACT CLAUSES**

■ 10. The authority citation for 48 CFR part 552 continues to read as follows:

Authority: 40 U.S.C. 121(c).

**552.215-71 [Removed and Reserved]**

■ 11. Remove and reserve section 552.215-71.

■ 12. Amend section 552.238-70 by revising the introductory text and the date of the provision; and removing from the end of the section “(End of clause)” and adding “(End of provision)” in its place.

**552.238-70 Identification of Electronic Office Equipment Providing Accessibility for the Handicapped.**

As prescribed in 538.273(b)(1), insert the following provision:

**Identification of Electronic Office Equipment Providing Accessibility for the Handicapped (Date)**

\* \* \* \* \*

■ 13. Amend section 552.238-71 by revising the section heading, the introductory text, and the clause heading to read as follows:

**552.238-71 Submission and Distribution of Authorized Federal Supply Schedule (FSS) Price Lists.**

As prescribed in 538.273(d)(1), insert the following clause:

**Submission and Distribution of Authorized Federal Supply Schedule (FSS) Price Lists (Date)**

\* \* \* \* \*

**552.238-72 [Amended]**

■ 14. Amend section 552.238-72 by removing from the introductory text

“538.273(a)(3)” and adding “538.273(d)(2)” in its place.

**552.238-73 [Amended]**

■ 15. Amend section 552.238-73 by removing from the introductory text “538.273(a)(4)” and adding “538.273(d)(3)” in its place.

**552.238-74 [Amended]**

■ 16. Amend section 552.238-74 by removing from the introductory text “538.273(b)(1)” and adding “538.273(d)(4)” in its place.

■ 17. Amend section 552.238-75 by:

■ a. Removing from the introductory text “538.273(b)(2)” and adding “538.273(d)(5)” in its place; and

■ b. Revising the date and introductory text of Alternate I to read as follows:

**552.238-75 Price Reductions.**

\* \* \* \* \*

Alternate I (Date): As prescribed in 538.273(d)(5) substitute the following paragraph:

\* \* \* \* \*

■ 18. Amend section 552.238-78 by—

■ a. Revising the date of the clause; and removing from paragraph (f)(2) “552.232-79” and adding “552.238-97” in its place (twice); and

■ b. Amending Alternate I by revising the date of the Alternate; and removing from paragraph (a)(8) “GSA” and adding “GSA/VA” in its place (twice).

The revisions read as follows:

**552.238-78 Scope of Contract (Eligible Ordering Activities).**

\* \* \* \* \*

**Scope of Contract (Eligible Ordering Activities) (Date)**

\* \* \* \* \*

Alternate I (Date). \* \* \*

■ 19. Amend section 552.238-81 by—

■ a. Removing from the introductory text “538.273(b)” and adding “538.273(d)(6)” in its place; and

■ b. Amending Alternate I by revising the introductory text to read as follows:

**552.238-81 Modification (Federal Supply Schedule).**

\* \* \* \* \*

Alternate I (Date): As prescribed in 538.273(d)(6)(i), add the following paragraph (f) to the basic clause:

\* \* \* \* \*

■ 20. Add sections 552.238-82 through 552.238-134 to read as follows:

**552.238.82 Delivery Schedule.**

As prescribed in 538.273(d)(7), insert the following clause:

**Delivery Schedule (Date)**

(a) Time of Delivery. The Contractor shall deliver to destination within the number of

calendar days after receipt of order (ARO) in the case of F.O.B. Destination prices; or to place of shipment in transit in the case of F.O.B. Origin prices, as set forth below. Offerors shall insert in the "Time of Delivery (days ARO)" column in the schedule of Items a definite number of calendar days within which delivery will be made. In no case shall

the offered delivery time exceed the Contractor's normal business practice. The Government requires the Contractor's normal delivery time, as long as it is less than the "stated" delivery time(s) shown below. If the Offeror does not insert a delivery time in the schedule of items, the Offeror will be deemed to offer delivery in accordance with the

Government's stated delivery time, as stated below [The contracting officer shall insert the solicited items or Special Item Numbers (SIN) as well as a reasonable delivery time that corresponds with each item or SIN, if known]:

Items or group of items (special item no. or nomenclature)	Government's stated delivery time (days ARO)	Contractor's delivery time
* _____ *	* _____ *	_____
* _____ *	* _____ *	_____
* _____ *	* _____ *	_____

(b) *Expedited Delivery Times.* For those items that can be delivered quicker than the delivery times in paragraph (a) of this clause, the Offeror is requested to insert below, a time (hours/days ARO) that delivery can be made when expedited delivery is requested.

Items or group of items (special item no. or nomenclature)	Expedited delivery time (hours/days ARO)
_____	_____
_____	_____
_____	_____

(c) *Overnight and 2-Day Delivery Times.* Ordering activities may require overnight or 2-day delivery. The Offeror is requested to annotate its price list or by separate attachment identify the items that can be delivered overnight or within 2 days. Contractors offering such delivery services will be required to state in the cover sheet to its FSS price list details concerning this service.

(End of clause)

**552.238-83 GSA ADVANTAGE!®**

As prescribed in 538.273(d)(8), insert the following clause:

**GSA Advantage!® (Date)**

(a) The Contractor shall participate in the GSA Advantage!® online shopping service. Information and instructions regarding Contractor participation are contained in clause 552.238-121, Electronic Commerce.

(b) The Contractor shall refer to contract clauses 552.238-71, Submission and Distribution of Authorized FSS Price Lists (which provides for submission of price lists on a common-use electronic medium), I-FSS-600, Contract Price Lists (which provides information on electronic contract data), and 552.238-81, Modifications (which addresses electronic file updates).

(End of clause)

**552.238-84 Cover Page for Federal Supply Schedules.**

As prescribed in 538.273(a)(1), insert the following provision:

**Cover Page for Federal Supply Schedules (Date)**

Solicitation No. [The contracting officer shall insert the solicitation number here] \* \_\_\_\_\_ \*

Geographic Area. [The contracting officer shall indicate whether the solicitation is CONUS or Worldwide] Federal Supply Schedule Contract for \* \_\_\_\_\_ \*.

[For supplies, the Contracting Officer shall complete the information required by paragraph (a) and delete paragraph (b) in its entirety. For services, the Contracting Officer shall complete the information required by paragraph (b) and delete (a) in its entirety. For solicitations containing both supplies and services, the Contracting Officer shall complete paragraphs (a) and (b).]

(a) Federal Supply Classification (FSC) GROUP: \* \_\_\_\_\_ \* PART: \* \_\_\_\_\_ \* SECTION: \* \_\_\_\_\_ \*

SUPPLY: \* \_\_\_\_\_ \* FSC CLASS(ES)/ PRODUCT CODE(S)/NAICS: \* \_\_\_\_\_ \*.

(b) STANDARD INDUSTRY GROUP: \* \_\_\_\_\_ \* SERVICE: \* \_\_\_\_\_ \* SERVICE CODE(S)/NAICS: \* \_\_\_\_\_ \*.

(End of provision)

*Alternate I (Date):* As prescribed at 538.237(a)(1), add the following paragraph (c) to the basic provision:

(c) PERIOD: \* \_\_\_\_\_ \* THROUGH \* \_\_\_\_\_ \*.

**552.238-85 Significant Changes.**

As prescribed in 538.273(a)(2), insert the following provision:

**Significant Changes (Date)**

The following significant changes have been made to the solicitation since the issuance of the last refresh: [The Contracting Officer shall insert the most recent solicitation revisions since its previous posting to the Government's point of entry \* \_\_\_\_\_ \*].

(End of provision)

**552.238-86 Notice of Total Small Business Set-Aside.**

As prescribed in 538.273(a)(3), insert the following provision:

**Notice of Total Small Business Set-Aside (Date)**

The clause entitled "Notice of Total Small Business Set-Aside," applies to the following: [The contracting officer shall insert the special item numbers (SINs) set aside for small businesses] \* \_\_\_\_\_ \*.

(End of provision)

**552.238-87 Information Collection Requirements.**

As prescribed in 538.273(a)(4), insert the following provision:

**Information Collection Requirements (Date)**

The information collection requirements contained in this solicitation/contract are either required by regulation or approved by the Office of Management and Budget pursuant to the Paperwork Reduction Act and assigned OMB Control No. 3090-0163.

(End of provision)

**552.238-88 Notice: Requests for Explanation or Information and Hours of Operation.**

As prescribed in 538.273(a)(5), insert the following provision:

**Notice: Requests for Explanation or Information and Hours of Operation (Date)**

(a) Oral or written requests for explanation or information regarding this solicitation shall be directed to [The contracting officer shall insert the contact information for the office responsible for responding to questions regarding the solicitation]: \* \_\_\_\_\_ \*; or Phone \* \_\_\_\_\_ \*; or Email: \* \_\_\_\_\_ \*.

\* IMPORTANT: DO NOT ADDRESS OFFERS, MODIFICATIONS OR WITHDRAWALS TO THE ABOVE ADDRESS. THE ADDRESS DESIGNATED FOR RECEIPT OF OFFERS IS CONTAINED ELSEWHERE IN THIS SOLICITATION.

(b) GSA's hours of operation are 8:00 a.m. to 4:30 p.m. eastern standard time.

(End of provision)

**552.238–89 Contractor's Remittance (Payment) Address.**

As prescribed in 538.273(b)(2), insert the following provision:

**Contractor's Remittance (Payment) Address (Date)**

(a) Payment by electronic funds transfer (EFT) is the preferred method of payment. However, under certain conditions, the ordering activity may elect to make payment by check. The Offeror shall indicate below the payment address to which checks shall be mailed for payment of proper invoices submitted under a resultant contract.

Payment Address:	

(b) Offeror shall furnish by attachment to this solicitation, the remittance (payment) addresses of all authorized participating dealers receiving orders and accepting payment by check in the name of the Contractor in care of the dealer, if different from their ordering address(es) specified elsewhere in this solicitation. If a dealer's ordering and remittance address differ, both must be furnished and identified as such.

(c) All Offerors are cautioned that if the remittance (payment) address shown on an actual invoice differs from that shown in paragraph (b) of this provision or on the attachment, the remittance address(es) in paragraph (b) of this provision or attached will govern. Payment to any other address, except as provided for through EFT payment methods, will require an administrative change to the contract.

**Note:** All orders placed against a Federal Supply Schedule contract are to be paid by the individual ordering activity placing the order. Each order will cite the appropriate ordering activity payment address, and proper invoices shall be sent to that address. Proper invoices shall be sent to GSA and/or VA only for orders placed by GSA and/or VA.

(End of provision)

**552.238–90 Introduction of New Supplies/Services (INSS).**

As prescribed in 538.273(b)(3), insert the following provision:

**Introduction of New Supplies/Services (INSS) (Date)**

(a) *Definition.* Introduction of New Supplies/Services Special Item Number (INSS SIN) means a new or improved supply or service—within the scope of the Federal Supply Schedule (FSS), but not currently available under any Federal Supply Schedule contract—that provides a new service, function, task, or attribute that may provide a more economical or efficient means for ordering activities to accomplish their missions. It may significantly improve an existing supply or service. It may be a supply or service existing in the commercial market,

but not yet introduced to the Federal Government.

(b) Offerors are encouraged to introduce new or improved supplies or services via INSS SIN at any time by clearly identify the INSS SIN item in the offer.

(c) The Contracting Officer has the sole discretion to determine whether a supply or service will be accepted as an INSS SIN item. The Contracting Officer will evaluate and process the offer and may perform a technical review. The INSS SIN provides temporary placement until the Contracting Officer formally categorizes the new supply or service.

(d) If the Contractor has an existing schedule contract, the Government may, at the sole discretion of the Contracting Officer, modify the existing contract to include the INSS SIN item in accordance with 552.238–81, Modifications (Federal Supply Schedules).

(End of provision)

**552.238–91 Authorized Negotiators.**

As prescribed in 538.273(b)(4), insert the following provision:

**Authorized Negotiators (Date)**

The offeror shall provide the names of all persons authorized to negotiate with the Government in connection with this request for proposals or quotations. (List the names, titles, telephone numbers and electronic mail address of the authorized negotiators.)

(End of provision)

**552.238–92 Evaluation—Commercial Items (Federal Supply Schedule)**

As prescribed in 538.273(c)(1), insert the following provision:

**Evaluation—Commercial Items (Federal Supply Schedule) (Date)**

(a) The Government may make multiple awards for the supplies or services offered in response to this solicitation that meet the definition of a "commercial item" in FAR 52.202–1. Awards may be made to those responsible offerors that offer reasonable pricing, conforming to the solicitation, and will be most advantageous to the Government, taking into consideration the multiplicity and complexity of items of various manufacturers and the differences in performance required to accomplish or produce required end results, production and distribution facilities, price, compliance with delivery requirements, and other pertinent factors. By providing a selection of comparable supplies or services, ordering activities are afforded the opportunity to fulfill their requirements with the item(s) that constitute the best value and that meet their needs at the lowest overall cost.

(b) A written notice of award or acceptance of an offer, mailed or otherwise furnished to the offeror within the time for acceptance specified in the offer, shall result in a binding contract without further action by either party. Before the offer's specified expiration time, the Government may accept an offer (or part of an offer), whether or not there are negotiations after its receipt, unless a written

notice of withdrawal is received before award.

(End of provision)

*Alternate 1 (Date):* As prescribed by 538.273(c)(1) add the following paragraph (c) to the basic provision:

(c) The Government reserves the right to award only one contract for all or a part of a manufacturer's product line. When two or more offerors (e.g., dealers/resellers) offer the identical product, award may be made competitively to only one offeror on the basis of the lowest price. (Discounts for early payment will not be considered as an evaluation factor in determining the low offeror). During initial open season for an option period, any offers that are equal to or lower than the current contract price received for identical items will be considered. Current Contractors will also be allowed to submit offers for identical items during this initial open season. The current Contractor which has the identical item on contract will be included in the evaluation process. The Government will evaluate all offers and may award only one contract for each specified product or aggregate group.

**552.238–93 Use of Non-Government Employees To Review Offers.**

As prescribed in 538.273(c)(2), insert the following provision:

**Use of Non-Government Employees to Review Offers (Date)**

(a) The Government may employ individual technical consultants/advisors/contractors from the below listed organizations to review limited portions of the technical, management and price proposals to assist the government in both pre-award and post-award functions. [*The Contracting Officer shall insert a list of organizations used to review solicitation responses and execute a non-disclosure and organizational conflict of interest statement for all individuals conducting reviews.*]

(b) These representatives will be used to advise on specific technical, management, and price matters and shall not, under any circumstances, be used as voting evaluators. However, the Government may consider the advice provided in its evaluation process. In addition, Contractor personnel may be used in specific contract administration tasks (e.g., administrative filing, review of deliverables, etc.).

(c) If individual technical consultants/advisors/contractors are utilized as described in paragraph (b) of this section, they will be required to execute a non-disclosure and organizational conflict of interest statements.

(End of provision)

**552.238–94 Examination of Records by GSA (Federal Supply Schedules).**

As prescribed in 538.273(d)(9) insert the following clause:

**Examination of Records by GSA (Federal Supply Schedules) (Date)**

The Contractor agrees that the Administrator of General Services or any

duly authorized representative shall have access to and the right to examine any books, documents, papers and records of the contractor involving transactions related to this contract for overbillings, billing errors, compliance with the Price Reduction clause and compliance with the Industrial Funding Fee and Sales Reporting clause of this contract. This authority shall expire 3 years after final payment. The basic contract and each option shall be treated as separate contracts for purposes of applying this clause.

(End of clause)

**552.238–95 Discounts for Prompt Payment (Federal Supply Schedules).**

As prescribed in 538.273(d)(10), insert the following clause:

**Discounts for Prompt Payment (Federal Supply Schedules) (Date)**

(a) Discounts for early payment (hereinafter referred to as “discounts” or “the discount”) will be considered in evaluating the relationship of the Offeror’s concessions to the Government vis-a-vis the Offeror’s concessions to its commercial and Federal non-schedule customers, but only to the extent indicated in this clause.

(b) Discounts will not be considered to determine the low Offeror in the situation described in the “Offers on Identical Products” provision of this solicitation.

(c) Uneconomical discounts will not be considered as meeting the criteria for award established by the Government. In this connection, a discount will be considered uneconomical if the annualized rate of return for earning the discount is lower than the “value of funds” rate established by the Department of the Treasury and published quarterly in the **Federal Register**. The “value of funds” rate applied will be the rate in effect on the date specified for the receipt of offers.

(d) Discounts for early payment may be offered either in the original offer or on individual invoices submitted under the resulting contract. Discounts offered will be taken by the ordering activity if payment is made within the discount period specified.

(e) Discounts that are included in offers become a part of the resulting contracts and are binding on the Contractor for all orders placed under the contract. Discounts offered only on individual invoices will be binding on the Contractor only for the particular invoice on which the discount is offered.

(f) In connection with any discount offered for prompt payment, time shall be computed from the date of the invoice. For the purpose of computing the discount earned, payment shall be considered to have been made on the date which appears on the payment check or the date on which an electronic funds transfer was made.

(End of clause)

**552.238–96 Contractor’s Billing Responsibilities.**

As prescribed in 538.273(d)(11) insert the following clause:

**Contractor’s Billing Responsibilities (Date)**

(a) The Contractor is required to perform all billings made pursuant to this contract. However, if the Contractor has dealers that participate on the contract and the billing/payment process by the Contractor for sales made by the dealer is a significant administrative burden, the following alternative procedures may be used. Where dealers are allowed by the Contractor to bill ordering activities and accept payment in the Contractor’s name, the Contractor agrees to obtain from all dealers participating in the performance of the contract a written agreement, which will require dealers to—

(1) Comply with the same terms and conditions as the Contractor for sales made under the contract;

(2) Maintain a system of reporting sales under the contract to the manufacturer, which includes—

(i) The date of sale;

(ii) The ordering activity to which the sale was made;

(iii) The service or supply/model sold;

(iv) The quantity of each service or supply/model sold;

(v) The price at which it was sold, including discounts; and

(vi) All other significant sales data.

(3) Be subject to audit by the Government, with respect to sales made under the contract; and

(4) Place orders and accept payments in the name of the Contractor in care of the dealer.

(b) An agreement between a Contractor and its dealers pursuant to this procedure will not establish privity of contract between dealers and the Government.

(End of clause)

**552.238–97 Payment by Credit Card.**

As prescribed in 538.1203(d)(12) insert the following clause:

**Payment by Credit Card (Date)**

(a) *Definitions.*

*Credit card or Charge card* means any credit or charge card used to pay for purchases, including the Government-wide Commercial Purchase Card.

*Government-wide commercial purchase card* means a uniquely numbered charge card issued by a Contractor under GSA’s Government-wide Contract for Fleet, Travel, and Purchase Card Services to named individual Government employees or entities to pay for official Government purchases.

*Oral order* means an order placed orally either in person or by telephone.

(b) The Contractor must accept credit and charge cards for payments equal to or less than the micro-purchase threshold (see Federal Acquisition Regulation 2.101) for oral or written orders under this contract.

(c) The Contractor and the ordering activity may agree to use of a credit or charge card for purchases in dollar amounts over the micro-purchase threshold, and the Government encourages the Contractor to accept payment by the credit or charge card. The dollar value of a credit or charge card transaction must not exceed the ordering activity’s established limit. If the Contractor will not accept payment by the credit or

charge card for an order exceeding the micro-purchase threshold, the Contractor must so advise the ordering agency within 24 hours of receipt of the order.

(d) The Contractor shall not process a transaction for payment through the credit or charge card clearinghouse until the purchased supplies have been shipped or services performed. Unless the credit or charge cardholder requests correction or replacement of a defective or faulty item under other contract requirements, the Contractor must immediately credit a cardholder’s account for items returned as defective or faulty.

(e) Payments made using the Government-wide commercial purchase card are not eligible for any negotiated prompt payment discount. Payment made using an ordering activity debit card shall receive the applicable prompt payment discount.

(End of clause)

**552.238–98 Warranty (Federal Supply Schedules).**

As prescribed in 538.1203(d)(13), insert the following clause:

**Warranty (Federal Supply Schedules) (Date)**

(a) Applicable to domestic locations. Unless specified otherwise in this contract, the Contractor’s standard warranty as stated in the Contractor’s price list applies to this contract.

(b) Applicable to overseas destinations. Unless specified otherwise in this contract, the Contractor’s standard warranty as stated in the price list applies to this contract, except as follows:

(1) The Contractor must provide, at a minimum, a warranty on all non-consumable parts for a period of 90 days from the date that the ordering activity accepts the supply.

(2) The Contractor must supply parts and labor required under the warranty provisions free of charge.

(3) The Contractor must bear the transportation costs of returning the supplies to and from the repair facility, or the costs involved with Contractor personnel traveling to the ordering activity facility for the purpose of repairing the supply onsite, during the 90-day warranty period.

(End of clause)

**552.238–99 Deliveries to the U.S. Postal Service.**

As prescribed in 538.273(d)(14), insert the following clause:

**Deliveries to the U.S. Postal Service (Date)**

(a) *Applicability.* This clause applies to orders placed for the U.S. Postal Service (USPS) and accepted by the Contractor for the delivery of supplies to a USPS facility (consignee).

(b) *Mode/Method of Transportation.* Unless the Contracting Officer grants a waiver of this requirement, any shipment that meets the USPS requirements for mailability (*i.e.*, 70 pounds or less, combined length and girth not more than 108 inches, etc.) delivery shall be accomplished via the use of the USPS. Other commercial services shall not be used, but this does not preclude the Contractor

from making delivery by the use of the Contractor's own vehicles.

(c) *Time of Delivery.* Notwithstanding the required time for delivery to destination as may be specified elsewhere in this contract, if shipments under this clause are mailed not later than five (5) calendar days before the required delivery date, delivery shall be deemed to have been made timely.

(End of clause)

#### **552.238-100 Characteristics of Electric Current.**

As prescribed in 538.273(d)(15), insert the following clause:

##### **Characteristics of Electric Current (Date)**

Contractors supplying equipment which uses electrical current are required to supply equipment suitable for the electrical system at the location at which the equipment is to be used as specified on the order.

(End of clause)

#### **552.238-101 Marking and Documentation Requirements for Shipping.**

As prescribed in 538.273(d)(16), insert the following clause:

##### **Marking and Documentation Requirements for Shipping (Date)**

(a) It shall be the responsibility of the ordering activity to determine the full marking and documentation requirements necessary under the various methods of shipment authorized by the contract. Set forth is the minimum information and documentation that will be required for shipment. In the event the ordering activity fails to provide the essential information and documentation, the Contractor shall, within three days after receipt of order, contact the ordering activity and advise them accordingly. The Contractor shall not proceed with any shipment requiring transshipment via U.S. Government facilities without the stated prerequisites:

(b) *Direct Shipments.* The Contractor shall mark all items ordered against this contract with indelible ink, paint or fluid, as follows:

- (1) Traffic Management or Transportation Officer at FINAL destination.
- (2) Ordering Supply Account Number.
- (3) Account number.
- (4) Delivery Order or Purchase Order Number.
- (5) National Stock Number, if applicable; or Contractor's item number.

(6) Box \_\_\_\_\_ of \_\_\_\_\_ Boxes.

(7) Nomenclature (brief description of items).

(End of clause)

#### **552.238-102 Inspection.**

As prescribed in 538.273(d)(17), insert the following clause:

##### **Inspection (Date)**

Inspection of all purchases under this contract will be made at destination by an authorized Government representative.

(End of clause)

*Alternate I (Date):* As prescribed by 538.273(d)(17), substitute the following for the basic clause:

(a) *Inspection by the Government.* It is anticipated that the supplies purchased under this contract will be inspected at destination by the Government to ensure conformance with technical requirements as specified herein.

(b) *Responsibility for Rejected Supplies.* If, after due notice of rejection, the Contractor fails to remove or provide instructions for the removal of rejected supplies pursuant to the Contracting Officer's instructions, the Contractor shall be liable for all costs incurred by the Government in taking such measures as are expedient to avoid unnecessary loss to the Contractor. In addition to any other remedies which may be available under this contract, the supplies may be stored for the Contractor's account or sold to the highest bidder on the open market and the proceeds applied against the accumulated storage and other costs, including the cost of the sale.

(c) *Additional Costs for Inspection and Testing.* (The Contracting Officer shall insert the rates). When prior rejection makes reinspection or retesting necessary, the following charges are applicable. When inspection or testing is performed by or under the direction of GSA, charges will be at the rate of \$ \_\_\_\_\_ per man-hour or fraction thereof if the inspection is at a GSA distribution center; \$ \_\_\_\_\_ per man-hour or fraction thereof, plus travel costs incurred, if the inspection is at another location; and \$ \_\_\_\_\_ per man-hour or fraction thereof for laboratory testing, except that when a testing facility other than a GSA laboratory performs all or part of the required tests, the Contractor shall be assessed the actual cost incurred by the Government as a result of testing at such facility. When inspection is performed by or under the direction of any agency other than GSA, the charges indicated above may be used, or the agency may assess the actual cost of performing the inspection and testing.

#### **552.238-103 Vendor Managed Inventory (VMI) Program.**

As prescribed in 538.273(d)(18), insert the following clause:

##### **Vendor Managed Inventory (VMI) Program (Date)**

(a) The term "Vendor Managed Inventory" describes a system in which the Contractor monitors and maintains specified inventory levels for selected items at designated stocking points. VMI enables the Contractor to plan production and shipping more efficiently. Stocking points benefit from reduced inventory but steady stock levels.

(b) Contractors that commercially provide a VMI type system may enter into similar partnerships with customers under a Blanket Purchase Agreement.

(End of clause)

#### **552.238-104 Order Acknowledgement.**

As prescribed in 538.273(d)(19), insert the following clause:

##### **Order Acknowledgement (Date)**

Contractors shall acknowledge only those orders which state "Order Acknowledgement Required". These orders shall be acknowledged within 10 calendar days after receipt. Such acknowledgement shall be sent to the ordering activity placing the order and contain information pertinent to the order, including the anticipated delivery date.

(End of clause)

#### **552.238-105 Urgent Requirements.**

As prescribed in 538.273(d)(20), insert the following clause:

##### **Urgent Requirements (Date)**

When the Federal Supply Schedule contract delivery period does not meet the bona fide urgent delivery requirements of an ordering activity, the ordering activity is encouraged, if time permits, to contact the Contractor for the purpose of obtaining accelerated delivery. The Contractor shall reply to the inquiry within three (3) business days after receipt. (Telephonic replies shall be confirmed by the Contractor in writing.) If the Contractor offers an accelerated delivery time acceptable to the ordering activity, any order(s) placed pursuant to the agreed upon accelerated delivery time frame shall be delivered within this shorter delivery time and in accordance with all other terms and conditions of the contract.

(End of clause)

#### **552.238-106 Post-Award Samples.**

As prescribed in 538.273(d)(21), insert the following clause:

##### **Post-Award Samples (Date)**

(a) Within 20 calendar days after approval of the brochure proof, Contractors who have received an award on carpet items are required to:

(1) Furnish the Contracting Officer with 5 sets (by sets, not loosely packed) of samples approximately 12 by 12 inches of all patterns and/or colors awarded;

(2) Furnish such additional sets of samples as may be requested during the contract period;

(3) Furnish a set of small cuttings approximately 3 by 5 inches of each quality carpet awarded to all ordering activities to which brochures are mailed, except that such sample cuttings need not be furnished when the brochure distributed by the Contractor was fully swatched with all available colors for each quality carpet awarded;

(4) Furnish sets of 3 by 5 inch samples to any ordering activity when specifically requested to do so notwithstanding the fact that the brochure was fully swatched; and

(5) Furnish the Contracting Officer with one 18 inch by 24 inch sample of each quality carpet and in each color or pattern covered by the contract, with the clear understanding that the Government reserves the right at its option to request one additional 18 inch by 24 inch sample in any one or all qualities in each pattern and/or color specified, and the Contractor agrees to honor such request. These samples will be returned at the Contractor's expense after

expiration of the contract provided they have not been consumed as a result of the Government's sample requirements.

(b) Each individual sample, or cutting, shall bear the Contractor's name, manufacturer's name, brand or quality name, pattern or color number and name, and the National Stock Number.

(End of clause)

**552.238-107 Restriction on the Acceptance of Orders.**

As prescribed in 538.273(d)(22), insert the following clause:

**Restriction on the Acceptance of Orders (Date)**

No orders shall be accepted from, and no deliveries shall be made to any ship of the United States Navy or the Military Sealift Command. This prohibition shall include all electrostatic copying equipment, supplies (toner, developer, fuser oil) for such equipment, repair or replacement parts for such equipment, and maintenance or repair service for such equipment.

(End of clause)

**552.238-108 Separate Charge for Performance Oriented Packaging (POP).**

As prescribed in 538.273(d)(23), insert the following clause:

**Separate Charge for Performance Oriented Packaging (POP) (Date)**

(a) Preservation, packaging, packing, and marking and labeling of domestic and overseas HAZMAT SURFACE SHIPMENTS shall comply with all requirements listed below. Offerors are requested to quote a separate charge, if applicable.

(1) International Maritime Dangerous Goods (IMDG) Code established by the International Maritime Organization (IMO) in accordance with the United Nations (UN) Recommendations on the Transportation of Dangerous Goods (Note: Marine pollutants must be labeled as required by the IMDG Code);

(2) The performance oriented packaging requirements contained in the U.S. Department of Transportation (DOT) Hazardous Materials Regulations (HMR; 49 CFR Parts 171 through 180) effective October 1, 1991 (Note: The "Combustible" and "ORM" classifications containing these requirements are not permitted by the IMDG Code and cannot be used);

(3) Occupational Safety and Health Administration (OSHA) Regulations 29 CFR Parts 1910.101 through 1910.120 and 1910.1000 through 1910.1500, relating to Hazardous and Toxic Substances; and

(4) Any preservation, packaging, packing, and marking and labeling requirements contained elsewhere in the solicitation.

(b) Offerors are requested to list the hazardous material item to which the separate charge applies in the spaces provided below or on a separate attachment. These separate charges will be accepted as part of the award, if considered reasonable, and shall be included in the Contractor's published catalog and/or price list.

Items (SINs or descriptive name of articles, as appropriate)	Charge for performance oriented packaging
_____	_____
_____	_____
_____	_____

(c) Ordering activities will not be obligated to utilize the Contractor's services for Performance Oriented Packaging, and they may obtain such services elsewhere if desired. However, the Contractor shall provide items in Performance Oriented Packaging when such packing is specified on the delivery order. The Contractor's contract price and the charge for Performance Oriented Packaging will be shown as separate entries on the delivery order.

(d) The test reports showing compliance with package requirements will be made available to contract administration/management representatives upon request.

(End of clause)

**552.238-109 Additional Service Charge for Delivery within Consignee's Premises.**

As prescribed in 538.273(d)(24), insert the following clause:

**Additional Service Charge for Delivery Within Consignee's Premises (Date)**

(a) Offerors are requested to insert, in the spaces provided below or by attachment hereto, a separate charge for "Delivery Within Consignee's Premises" applicable to each shipping container to be shipped. (Articles which are comparable in size and weight, and for which the same charge is applicable, shall be grouped under an appropriate item description.) These additional charges will be accepted as part of the award, if considered reasonable, and shall be included in the Contractor's published catalog and/or price list.

(b) Ordering activities are not obligated to issue orders on the basis of "Delivery Within Consignee's Premises," and Contractors may refuse delivery on that basis provided such refusal is communicated in writing to the ordering activity issuing such orders within

5 days of the receipt of such order by the Contractor and provided further, that delivery is made in accordance with the other delivery requirements of the contract. Failure of the Contractor to submit this notification within the time specified shall constitute acceptance to furnish "Delivery Within Consignee's Premises" at the additional charge awarded. When an ordering activity issues an order on the basis of "Delivery Within Consignee's Premises" at the accepted additional charge awarded and the Contractor accepts such orders on that basis, the Contractor will be obligated to provide delivery "F.o.b. Destination, Within Consignee's Premises" in accordance with FAR 52.247-35, which is then incorporated by reference, with the exception that an additional charge as provided herein is allowed for such services. Unless otherwise stipulated by the Offeror, the additional charges awarded hereunder may be applied to any delivery within the 48 contiguous States and the District of Columbia.

(c) When exercising their option to issue orders on the basis of delivery service as provided herein, ordering activities will specify "Delivery Within Consignee's Premises" on the order, and will indicate the exact location to which delivery is to be made. The Contractor's delivery price and the additional charge(s) for "Delivery Within Consignee's Premises" will be shown as separate entries on the order.

Items (NSN's or special item numbers or descriptive name of articles)	Additional charge (per shipping container) for "delivery within consignee's premises"
_____	_____
_____	_____
_____	_____

(End of clause)

**552.238-110 Shipping Points.**

As prescribed in 538.273(d)(25), insert the following clause:

**Shipping Points (Date)**

The Contractor awarded f.o.b. origin (or f.o.b. shipping point) prices shall indicate, in the spaces provided below, on in a separate attachment, the complete address (street, city, and state) from which the items will be shipped, and the name of the carrier serving point (if any). If more than one shipping point is designated for an item, ordering activities will have the option of specifying the shipping point unless otherwise noted by the Contractor.

Item Nos.	Name of facility	Address	Carrier
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____

(End of clause)

**552.238-111 Contact for Contract Administration.**

As prescribed in 538.273(d)(26), insert the following clause:

**Contact for Contract Administration (Date)**

(a) Offerors shall complete paragraphs (c) and (d) of this clause if providing both domestic and overseas delivery. Complete paragraph (c) of this clause if providing domestic delivery only. Complete paragraph (d) of this clause if providing overseas delivery only.

(b) The Contractor shall designate a person to serve as the contract administrator for the contract both domestically and overseas. The contract administrator is responsible for overall compliance with contract terms and conditions. The contract administrator is also the responsible official for issues concerning 552.238-74, Industrial Funding Fee and Sales Reporting, including reviews of Contractor records. The Contractor's designated representative to handle certain functions under this contract does not relieve the contract administrator of responsibility for contract compliance. Any changes to the designated individual must be provided to the Contracting Officer in writing, with the proposed effective date of the change.

(c) *Domestic:*

NAME \_\_\_\_\_  
TITLE \_\_\_\_\_  
ADDRESS \_\_\_\_\_  
ZIP CODE \_\_\_\_\_  
TELEPHONE NO. \_\_\_\_\_  
FAX NO. \_\_\_\_\_  
E-MAIL ADDRESS \_\_\_\_\_

(d) *Overseas:* Overseas contact points are mandatory for local assistance with the resolution of any delivery, performance, or quality complaints from customer agencies. The designated representative shall be available during the local business hours in the country of delivery, even though the designated representative does not have to be located in the country of delivery. (Also, see the requirement in 552.238-113, Parts and Service.) A designated representative must be furnished for each area in which deliveries are contemplated, e.g., Europe, South America, Far East, etc.

LOCATION(S) COVERED \_\_\_\_\_  
NAME \_\_\_\_\_  
TITLE \_\_\_\_\_  
ADDRESS \_\_\_\_\_  
ZIP CODE \_\_\_\_\_  
TELEPHONE NO. \_\_\_\_\_  
FAX NO. \_\_\_\_\_  
E-MAIL ADDRESS \_\_\_\_\_

(End of clause)

**552.238-112 Clauses for Overseas Coverage.**

As prescribed in 538.273(d)(27), insert the following clause:

**Clauses for Overseas Coverage (Date)**

The following clauses apply to overseas coverage:

(a) 52.214-34; Submission of Offers in the English Language;

(b) 52.214-35; Submission of Offers in U.S. Currency;

(c) 52.247-34; FOB Destination;  
(d) 52.247-38; FOB Inland Carrier, Country of Exportation;

(e) 52.247-39; FOB Inland Point, Country of Importation;

(f) 552.238-100; Characteristics of Electric Current;

(g) 552.238-101; Marking and Documentation Requirements Per Shipment;

(h) 552.238-113; Parts and Service;

(i) 552.238-114; Delivery Prices Overseas;

(j) 552.238-115; Transshipments; and

(k) 552.238-116; Foreign Taxes and Duties.

(End of clause)

**552.238-113 Parts and Service.**

As prescribed in 538.273(d)(27)(viii), insert the following clause:

**Parts and Service (Date)**

(a) For equipment under items listed in the schedule of items or services on which offers are submitted, the Contractor represents by submission of this offer that parts and services (including the performing of warranty or guarantee service) are now available from dealers or distributors serving the areas of ultimate overseas destination or that such facilities will be established and will be maintained throughout the contract period. If a new servicing facility is to be established, the facility shall be established no later than the beginning of the contract period.

(b) Each Contractor shall be fully responsible for the services to be performed by the named servicing facilities, or by such facilities to be established, and fully guarantees performance of such services if the original service proves unsatisfactory.

(c) Contractors are requested to include in the price list, the names and addresses of all supply and service points maintained in the geographic area in which the Contractor will perform. Please indicate opposite each point whether or not a complete stock of repair parts for items offered is carried at that point, and whether or not mechanical service is available.

(End of clause)

**552.238-114 Delivery Prices Overseas.**

As prescribed in 538.273(d)(27)(ix), insert the following clause:

**Delivery Prices Overseas (Date)**

(a) Prices offered must cover delivery to destinations as provided below:

(1) Direct delivery to consignee. F.O.B. Inland Point, Country of Importation (FAR 52.247-39). (Offeror shall indicate countries where direct delivery will be provided.)

(2) Delivery to overseas assembly point for transshipment when specified by the ordering activity, if delivery is not covered under paragraph (a), of this section.

(3) Delivery to the overseas port of entry when delivery is not covered under paragraphs (a) or (b), of this section.

(b) Geographic area(s)/countries/zones which are intended to be covered must be identified in the offer.

(End of clause)

**552.238-115 Transshipments.**

As prescribed in 538.273(d)(27)(x), insert the following clause:

**Transshipments (Date)**

The Contractor shall complete two DD Forms 1387, Military Shipment Labels and, if applicable, four copies of DD Form 1387-2, Special Handling/Data Certification—used when shipping chemicals, dangerous cargo, etc. Two copies of the DD Form 1387 will be attached to EACH shipping container delivered to the port Transportation Officer for subsequent transshipment by the Government as otherwise provided for under the terms of this contract. These forms will be attached to one end and one side (NOT on the top or bottom) of the container. The Contractor will complete the bottom line of these forms, which pertains to the number of pieces, weight and cube of each piece, using U.S. weight and cubic measures. Weights will be rounded off to the nearest pound. (One kg = 2.2 U.S. pounds; one cubic meter = 35.3156 cubic feet.) In addition, if the cargo consists of chemicals, or is dangerous, one copy of the DD Form 1387 2 will be attached to the container, and three copies will be furnished to the Transportation Officer with the Bill of Lading. DANGEROUS CARGO WILL NOT BE INTERMINGLED WITH NONDANGEROUS CARGO IN THE SAME CONTAINER. Copies of the above forms and preparation instructions will be obtained from the ordering activity issuing the Delivery Order. Reproduced copies of the forms are acceptable. FAILURE TO INCLUDE DD FORMS 1387 (AND DD FORM 1387-2, IF APPLICABLE) ON EACH SHIPPING CONTAINER WILL RESULT IN REJECTION OF SHIPMENT BY THE PORT TRANSPORTATION OFFICER.

(End of clause)

**552.238-116 Foreign Taxes and Duties.**

As prescribed in 538.273(d)(27)(xi), insert the following clause:

**Foreign Taxes and Duties (Date)**

Prices offered must be net, delivered, f.o.b. to the destinations accepted by the Government.

(a) The Contractor warrants that such prices do not include any tax, duty, customs fees, or other foreign Governmental costs, assessments, or similar charges from which the U.S. Government is exempt.

(b) Standard commercial export packaging, including containerization, if necessary, packaging, preservation, and/or marking are included in the pricing offered and accepted by the Government.

(End of clause)

**552.238-117 English Language and U.S. Dollar Requirements.**

As prescribed in 538.273(d)(28), insert the following clause:

**English Language and U.S. Dollar Requirements (Date)**

(a) All documents produced by the Contractor to fulfill requirements of this contract including, but not limited to,

Federal Supply Schedule catalogs and price lists, must reflect all terms and conditions in the English language.

(b) U.S. dollar equivalency, if applicable, will be based on the rates published in the "Treasury Reporting Rates of Exchange" in effect as of the date of the agency's purchase order or in effect during the time period specified elsewhere in this contract.

(End of clause)

#### 552.238-118 Delivery Prices.

As prescribed in 538.273(d)(29), insert the following clause:

##### Delivery Prices (Date)

(a) Prices offered must cover delivery as provided below to destinations located within the 48 contiguous States and the District of Columbia.

(1) Delivery to the door of the specified Government activity by freight or express common carriers on articles for which store-door delivery is provided, free or subject to a charge, pursuant to regularly published tariffs duly filed with the Federal and/or State regulatory bodies governing such carrier; or, at the option of the Contractor, by parcel post on mailable articles, or by the Contractor's vehicle. Where store-door delivery is subject to a charge, the Contractor shall—

(i) Place the notation "Delivery Service Requested" on bills of lading covering such shipments; and

(ii) Pay such charge and add the actual cost thereof as a separate item to his invoice.

(2) Delivery to siding at destinations when specified by the ordering office, if delivery is not covered under paragraph (a)(1), of this section.

(3) Delivery to the freight station nearest destination when delivery is not covered under paragraph (a)(1) or (a)(2) of this section.

(b) The Offeror shall indicate in the offer whether or not prices submitted cover delivery f.o.b. destination in Alaska, Hawaii, and the Commonwealth of Puerto Rico.

(c) When deliveries are made to destinations outside the contiguous 48 States; i.e., Alaska, Hawaii, and the Commonwealth of Puerto Rico, and are not covered by paragraph (b), above, the following conditions will apply:

(1) Delivery will be f.o.b. inland carrier, point of exportation (FAR 52.247-38), with the transportation charges to be paid by the Government from point of exportation to destination in Alaska, Hawaii, or the Commonwealth of Puerto Rico, as designated by the ordering office. The Contractor shall add the actual cost of transportation to destination from the point of exportation in the 48 contiguous States nearest to the designated destination. Such costs will, in all cases, be based upon the lowest regularly established rates on file with the Interstate Commerce Commission, the U.S. Maritime Commission (if shipped by water), or any State regulatory body, or those published by the U.S. Postal Service; and must be supported by paid freight or express receipt or by a statement of parcel post charges including weight of shipment.

(2) The right is reserved to ordering agencies to furnish Government bills of lading.

(End of clause)

#### 552.238-119 Federal Excise Tax.

As prescribed in 538.1203(d)(30), insert the following clause:

##### Federal Excise Tax (Date)

Prices offered shall exclude Federal Excise Tax. Ordering agencies will be notified that the Federal Excise Tax will be invoiced and paid for by them as a separate item based upon published Rubber Manufacturer's Association average weights effective at time of delivery, unless the ordering activity is exempt from such tax.

(End of clause)

#### 552.238-120 Guarantee.

As prescribed in 538.273(d)(31), insert the following clause:

##### Guarantee (Date)

The Contractor guarantees the equipment furnished will be free from defects in material and workmanship for a period of not less than 1 year from date of delivery. All parts found defective within that period shall be replaced, with the cost of replacement, including shipping charges, to be borne by the Contractor. Under no circumstances will any equipment covered by this guarantee be returned without:

(a) Advance written notice to the Contractor; or

(b) Obtaining shipping instructions from the Contractor.

(End of clause)

#### 552.238-121 Electronic Commerce.

As prescribed in 538.273(d)(32), insert the following clause:

##### Electronic Commerce (Date)

(a) *General Background.* The Federal Acquisition Streamlining Act (FASA) of 1994 requires the Government to evolve its acquisition process from one driven by paper to an expedited process based on electronic commerce/electronic data interchange (EC/EDI). EC/EDI encompasses more than merely automating manual processes and eliminating paper transactions. EC/EDI improves business processes (e.g. procurement, finance, logistics) into a fully electronic environment and fundamentally changes the way organizations operate.

(b) *Trading Partners and Value-Added Networks/Services (VANs/VASs).*

(1) Within the electronic commerce architecture, electronic documents (e.g., orders, invoices, etc.) are carried between the Federal Government's procuring office and Contractors (now known as "trading partners"). These transactions are carried by 3rd party commercial telecommunications companies called Value-Added Networks/Services (VANs/VASs).

(2) EC/EDI can be performed using commercially available hardware, software, and telecommunications. The selection of a VAN/VAS is a business decision Contractors

must make. There are many different providers which provide a variety of electronic services and different pricing strategies. If the provider only provides communications services, you may also need a software translation package.

(c) *Registration Instructions.* To perform EC/EDI with the Government, Contractors shall register as a trading partner. Contractors will provide regular business information, banking information, and EC/EDI capabilities to all agencies in this single registration. A central repository of all trading partners is the Systems for Award Management (SAM) <http://www.sam.gov>. Contractors shall follow the instructions on the SAM Web site regarding how to register for EC/EDI.

(d) *Implementation Conventions.* All EDI transactions must comply with the Federal Implementation Conventions (ICs). The ICs are available on a registry maintained by the National Institute of Standards and Technology (NIST). It is accessible via the Internet at <http://www.nist.gov/itl>. ICs are available for common business documents such as Purchase Order, Price Sales Catalog, Invoice, Request for Quotes, etc.

(e) *Additional Information.* GSA has additional information available for Contractors who are interested in using EC/EDI on its Web site, [www.gsa.gov](http://www.gsa.gov).

(f) *GSA Advantage!®.* (1) GSA Advantage!® uses electronic commerce to receive catalogs and text messages; and to send purchase orders, application advice, and functional acknowledgments. GSA Advantage!® enables customers to:

(i) Perform database searches across all contracts by manufacturer; manufacturer's model/part number; Contractor; and generic supply categories;

(ii) Generate EDI/XML delivery orders to Contractors, generate EDI/XML delivery orders from the Federal Acquisition Service to Contractors, or download files to receive delivery orders; and

(iii) Use the credit card.

(2) GSA Advantage!® may be accessed via the GSA Home Page. The INTERNET address is: <http://www.gsa.gov>.

(End of clause)

#### 552.238-122 Imprest Funds (Petty Cash).

As prescribed in 538.273(d)(33), insert the following clause:

##### Imprest Funds (Petty Cash) (Date)

The Contractor agrees to accept cash payment for purchases made under the terms of the contract in conformance with Federal Acquisition Regulation (FAR) 13.305.

(End of clause)

#### 552.238-123 Dissemination of Information by Contractor.

As prescribed in 538.273(d)(34), insert the following clause:

##### Dissemination of Information by Contractor (Date)

The Government will provide the Contractor with a single copy of the resulting Federal Supply Schedule contract award documents. However, it is the responsibility

of the Contractor to furnish all sales outlets authorized to participate in the performance of the contract with the terms, conditions, pricing schedule, and other appropriate information.

(End of clause)

**552.238–124 Deliveries Beyond the Contractual Period—Placing of Orders.**

As prescribed in 538.273(d)(35), insert the following clause:

**Deliveries Beyond the Contractual Period—Placing of Orders (Date)**

In accordance with clause 552.238–78, Scope of Contract (Eligible Ordering Activities), this contract covers all requirements that may be ordered, as distinguished from delivered during the contract term. This is for the purpose of providing continuity of supply or operations by permitting ordering activities to place orders as requirements arise in the normal course of operations. Accordingly, any order mailed (or received, if forwarded by other means than through the mail) to the Contractor on or before the expiration date of the contract, and providing for delivery within the number of days specified in the contract, shall constitute a valid order.

(End of clause)

**552.238–125 Interpretation of Contract Requirements.**

As prescribed in 538.273(d)(36), insert the following clause:

**Interpretation of Contract Requirements (Date)**

No interpretation of any provision of this contract, including applicable specifications, shall be binding on the Government unless furnished or agreed to in writing by the Contracting Officer or his designated representative.

(End of clause)

**552.238–126 Export Traffic Release (Supplies).**

As prescribed in 538.273(d)(37), insert the following clause:

**Export Traffic Release (Supplies) (Date)**

Supplies ordered by GSA for export will not be shipped by the Contractor until shipping instructions are received from GSA. To obtain shipping instructions, the Contractor shall forward completed copies of GSA Form 1611, Application for Shipping Instructions and Notice of Availability, to the GSA office designated on the purchase order at least 15 days prior to the anticipated shipping date. Copies of GSA Form 1611 will be furnished to the Contractor with the purchase order. Failure to comply with this requirement could result in nonacceptance of the material by authorities at the port of exportation. When supplies for export are ordered by other Government agencies the Contractor shall obtain shipping instructions from the ordering agency.

(End of clause)

**552.238–127 Export Traffic Release (Vehicles).**

As prescribed in 538.273(d)(38), insert the following clause:

**Export Traffic Release (Vehicles) (Date)**

Shipment of vehicles for export will not be accepted without a release (clearance). To obtain this clearance, the contractor shall complete GSA Form 1611, "Application for Shipping Instructions and Notice of Availability," which can be obtained at the following Web site: <http://www.gsa.gov/portal/forms/type/GSA>.

Thirty (30) days in advance of the anticipated date of availability for shipment, the Contractor is to submit a completed GSA Form 1611, including vehicle identification (VIN) number(s) for each export destination, to the Transportation Office designated on the delivery order. Shipment is not to be made until instructions are received from the above transportation office. Failure to adhere to this requirement shall result in refusal of shipment until proper release is obtained. Distribution instructions are provided with the form.

(End of clause)

**552.238–128 Carload Shipments.**

As prescribed in 538.273(d)(39), insert the following clause:

**Carload Shipments (Date)**

When shipment is to be made by rail, to one destination, of a carload quantity which includes an item or items the overall length of which when packed and/or palletized, is 60 inches or over, the Contractor shall, when ordering cars, specify that, if available, double-door rail cars be furnished. This provision is intended solely to facilitate unloading by forklift truck at destination. Under no circumstances shall scheduled shipment be delayed due to nonavailability of double-door cars.

(End of clause)

**552.238–129 Spare Parts Kit.**

As prescribed in 538.273(d)(40), insert the following clause:

**Spare Parts Kit (Date)**

(a) The Contractor will be required to offer a spare parts kit conforming, generally, to the following requirements for each item awarded under this solicitation: *[The contracting officer shall insert the specifications for a spare parts kit specific to the solicited items.] \* \* \**

(b) The Contractor shall furnish prices for spare parts kits as follows:

- (i) Price of kit unpackaged;
- (ii) Price of kit in domestic pack; and
- (iii) Price of kit in wooden case, steel-strapped.

(c) The Contractor will be required to furnish a complete description of spare parts kit offered, a list of parts included, and the price of the kit delivered f.o.b. destination to any point within the conterminous United States within 15 days after receipt of a request from the Contracting Officer. If the kit offered is acceptable to the Government,

awards covering requirements will be made by supplemental agreement to this contract.

(End of clause)

**552.238–130 Authentication Supplies and Services.**

As prescribed in 538.273(d)(41), insert the following clause:

**Authentication Supplies and Services (Date)**

(a) *General Background.* (1) The General Services Administration (GSA) originally established the Access Certificates for Electronic Services (ACES) Program to provide digital certificates and PKI services for enabling e-Government applications that require logical access control, digital signature and/or electronic authentication. This category of supplies and services has been expanded beyond the original scope of ACES and is now described as "Identity and Access Management" (IAM) to clearly define the kinds of services that meet the requirements for service providers and supplies that support FISMA-compliant IAM systems deployed by Federal agencies.

(2) Homeland Security Presidential Directive 12 (HSPD–12), "Policy for a Common Identification Standard for Federal Employees and Contractors" establishes the requirement for a mandatory Government-wide standard for secure and reliable forms of identification issued by the Federal Government to its employees and Contractor employees assigned to Government contracts in order to enhance security, increase Government efficiency, reduce identity fraud, and protect personal privacy. Further, the Directive requires the Department of Commerce to promulgate a Federal standard for secure and reliable forms of identification within six months of the date of the Directive. As a result, the National Institute of Standards and Technology (NIST) released Federal Information Processing Standard (FIPS) 201: Personal Identity Verification of Federal Employees and Contractors on February 25, 2005. FIPS 201 requires that the digital certificates incorporated into the Personal Identity Verification (PIV) identity credentials comply with the X.509 Certificate Policy for the U.S. Federal PKI Common Policy Framework. In addition, FIPS 201 requires that Federal identity badges referred to as PIV credentials, issued to Federal employees and Contractors comply with the Standard and associated NIST Special Publications 800–73, 800–76, 800–78, and 800–79.

(b) *Special Item Numbers.* GSA has established the e-Authentication Initiative (see URL: <http://www.idmanagement.gov>) to provide common infrastructure for the authentication of the public and internal federal users for logical access to Federal e-Government applications and electronic services. To support the government-wide implementation of HSPD–12 and the Federal e-Authentication Initiative, GSA has established Special Item Numbers (SINs) pertaining to Authentication Products and Services, including Electronic Credentials, Digital Certificates, eAuthentication, Identify and Access Management, PKI Shared Service Providers, and HSPD–12 Product and Service Components.

(c) *Qualification Information.* (1) All Authentication supplies and services must be qualified as being compliant with Government-wide requirements before they will be included on a GSA Information Technology (IT) Schedule contract. The Qualification Requirements and associated evaluation procedures against the Qualification Requirements for each SIN and the specific Qualification Requirements for HSPD-12 implementation components are presented at the following URL: <http://www.idmanagement.gov>.

(2) In addition, the National Institute of Standards and Technology (NIST) has established the NIST Personal Identity Verification Program (NPIVP) to evaluate integrated circuit chip cards and supplies against conformance requirements contained in FIPS 201. GSA has established the FIPS 201 Evaluation Program to evaluate other supplies needed for agency implementation of HSPD-12 requirements where normative requirements are specified in FIPS 201 and to perform card and reader interface testing for interoperability. Products that are approved as FIPS-201 compliant through these evaluation and testing programs may be offered directly through HSPD-12 Supplies and Services Components SIN under the category "Approved FIPS 201-Compliant Products and services".

(d) *Qualification Requirements.* Offerors proposing Authentication supplies and services under the established SINs are required to provide the following:

(1) Proposed items must be determined to be compliant with Federal requirements for that SIN. Qualification Requirements and procedures for the evaluation of supplies and services are posted at the URL: <http://www.idmanagement.gov>. GSA will follow these procedures in qualifying offeror's supplies and services against the Qualification Requirements for applicable to SIN. Offerors must submit all documentation certification letter(s) for Authentication Supplies and Services offerings at the same time as submission of proposal. Award will be dependent upon receipt of official documentation from the Acquisition Program Management Office (APMO) listed below verifying satisfactory qualification against the Qualification Requirements of the proposed SIN(s).

(2) After award, Contractor agrees that certified supplies and services will not be offered under any other SIN on any Federal Supply Schedule.

(3)(i) If the Contractor changes the supplies or services previously qualified, GSA may require the Contractor to resubmit the supplies or services for re-qualification.

(ii) If the Federal Government changes the qualification requirements or standards, Contractor must resubmit the supplies and services for re-qualification.

(4) Immediately prior to making an award, Contracting Officers MUST consult the following Web site to ensure that the supplies and/or services recommended for award under any Authentication Supplies and Services SINs are in compliance with the latest APL qualification standards: [www.idmanagement.gov](http://www.idmanagement.gov). A dated copy of the applicable page shall be made and included with the award documents.

(e) *Demonstrating Conformance.* The Federal Government has established Qualification Requirements for demonstrating conformance with the Standards. The following Web sites provide additional information regarding the evaluation and qualification processes:

(1) For Access Certificates for Electronic Services (ACES) and PKI Shared Service Provider (SSP) Qualification Requirements and evaluation procedures: <http://www.idmanagement.gov>.

(2) For HSPD-12 Product and Service Components Qualification Requirements and evaluation procedures: <http://www.idmanagement.gov>.

(3) For FIPS 201 compliant products and services qualification and approval procedures: <http://www.csrc.nist.gov/piv-project> and <http://www.smart.gov>.

(f) *Acquisition Program Management Office (APMO).* GSA has established the APMO to provide centralized technical oversight and management regarding the qualification process to industry partners and Federal agencies. Contact the following APMO for information on the eAuthentication Qualification process. Technical, APMO, FIPS 201, and HSPD-12 Points of Contact can be found below, or in an additional attachment to the solicitation. [The contracting officer shall insert the points of contact information below, unless otherwise included elsewhere in the solicitation.] \* \_\_\_\_\_ \*

(End of clause)

#### **552.238-131 Commercial Satellite Communication (COMSATCOM) Services.**

As prescribed in 538.273(d)(42) insert the following clause:

##### **Commercial Satellite Communication (COMSATCOM) Services (Date)**

(a) *General Background.* Special Item Numbers (SINs) have been established for Commercial Satellite Communications (COMSATCOM) services, focused on transponded capacity (SIN 132-54) and fixed and mobile subscription services (SIN 132-55), to make available common COMSATCOM services to all Ordering Activities.

(b) *Information Assurance.* (1) The Contractor shall demonstrate, to the maximum extent practicable, the ability to meet:

(i) The Committee on National Security Systems Policy (CNSSP) 12, "National Information Assurance Policy for Space Systems used to Support National Security Missions"; or

(ii) Department of Defense Directive (DoDD) 8581.1, "Information Assurance (IA) Policy for Space Systems Used by the Department of Defense."

(2) The Contractor shall demonstrate the ability to comply with the Federal Information Security Management Act of 2002 as implemented by Federal Information Processing Standards Publication 200 (FIPS 200), "Minimum Security Requirements for Federal Information and Information Systems." In response to ordering activity requirements, at a minimum, all services shall meet the requirements assigned against:

(i) A low-impact information system (per FIPS 200) that is described in the current revision of National Institute of Standards and Technology (NIST) Special Publication (SP) 800-53, "Recommended Security Controls for Federal Information Systems and Organizations;" or

(ii) A Mission Assurance Category (MAC) III system that is described in the current revision of DoD Instruction (DoDI) 8500.2, "Information Assurance Implementation."

(3) The Contractor's information assurance boundary is where the Contractor's services connect to the user terminals/equipment (*i.e.*, includes satellite command encryption (ground and space); systems used in the Satellite Operations Centers (SOCs), Network Operations Centers (NOCs) and teleport; and terrestrial infrastructure required for service delivery).

(c) *Delivery Schedule.* The Contractor shall deliver COMSATCOM services in accordance with 552.238-78.

(d) *Portability.* The Contractor shall have the capability to redeploy COMSATCOM services, subject to availability. Portability shall be provided within the COMSATCOM Contractor's resources at any time as requested by the ordering activity. When portability is exercised, evidence of equivalent net present value (NPV) shall be provided by the Contractor.

(e) *Flexibility/Optimization.* The Contractor shall have the capability to re-groom resources for spectral, operational, or price efficiencies. Flexibility/optimization shall be provided within the COMSATCOM Contractor's resources at any time as requested by the ordering activity. When flexibility/optimization is exercised, evidence of equivalent net present value (NPV) shall be provided by the Contractor. The Contractor is encouraged to submit re-grooming approaches for ordering activity consideration that may increase efficiencies for existing COMSATCOM services.

(f) *Net Ready (Interoperability).* COMSATCOM services shall be consistent with commercial standards and practices. Services shall have the capability to access and/or interoperate with Government or other Commercial teleports/gateways and provide enterprise service access to or among networks or enclaves. Interfaces may be identified as interoperable on the basis of participation in a sponsored interoperability program.

(g) *Network Monitoring (Net OPS).* The Contractor shall have the capability to electronically collect and deliver near real-time monitoring, fault/incident/outage reporting, and information access to ensure effective and efficient operations, performance, and availability, consistent with commercial practices. Consistent with the Contractor's standard management practices, the Net Ops information will be provided on a frequency (example: every 6 hours, daily) and format (example: SNMP, XML) as defined in a requirement to a location/entity/electronic interface defined by the ordering activity. Specific reporting requirements will be defined by the Ordering Activity.

(h) *EMI/RFI Identification, Characterization, and Geo-location.* The

Contractor shall have the capability to collect and electronically report in near real-time Electro Magnetic Interference (EMI)/Radio Frequency Interference (RFI) identification, characterization, and geo-location, including the ability to identify and characterize sub-carrier EMI/RFI being transmitted underneath an authorized carrier, and the ability to geo-locate the source of any and all EMI/RFI. The Contractor shall establish and use with the ordering activity a mutually agreed upon media and voice communications capability capable of protecting "Sensitive, but Unclassified" data.

(i) *Security.* (1) The Contractor may be required to obtain/possess varying levels of personnel and facility security clearances up to U.S. Government TOP SECRET/Sensitive Compartmented Information (TS/SCI) or equivalent clearances assigned by the National Security Authority of a NATO Member State or Major Non-NATO Ally.

(2) For incident resolution involving classified matters, the Contractor shall provide appropriately cleared staff who can affect COMSATCOM services operations (example: satellite payload operations, network operations). The Contractor shall provide a minimum of one operations staff member AND a minimum of one person with the authority to commit the company if resolution requires business impacting decisions (example: Chief Executive Officer, Chief Operations Officer, etc.).

(3) When Communications Security or Transmission Security equipment or keying material is placed in the equipment/terminal shelter, the Contractor shall ensure compliance with applicable physical security directives/guidelines and that all deployed equipment/terminal operations and maintenance personnel shall possess the appropriate clearances, equal to or higher than the classification level of the data being transmitted. Where local regulations require

use of foreign personnel for terminal operations and maintenance, then the Contractor shall ensure compliance with applicable security directives/guidelines and document to the U.S. Government's satisfaction that protective measures are in place and such individuals have equivalent clearances granted by the local host nation.

(4) For classified operations security (OPSEC), the Contractor shall ensure that all personnel in direct contact with classified OPSEC indicators (example: the unit, location, and time of operations) have U.S. SECRET or higher personnel security clearances, or, as appropriate, equivalent clearances assigned by the National Security Authority of a NATO Member State or Major Non-NATO Ally, in accordance with applicable security directives and guidelines.

(5) For classified requirements, cleared satellite operator staff must have access to secure voice communications for emergency purposes. Communications security equipment certified by the National Security Agency (NSA) to secure unclassified and up to and including SECRET communication transmissions at all operations centers is preferred. If a Contractor is unable to have access to NSA-approved communications security equipment at its operations centers, then a combination of a "Sensitive but Unclassified" (SBU) cryptographic module approved by the U.S. National Institute for Standards and Technology and pre-arranged access to National Security Agency-approved communications security equipment at an agreed alternate facility is acceptable.

(6) The Contractor shall have the capability to "mask" or "protect" users against unauthorized release of identifying information to any entity that could compromise operations security. Identifying information includes but is not limited to personal user and/or unit information including tail numbers, unit names, unit

numbers, individual names, individual contact numbers, street addresses, etc.

(j) Third party billing for COMSATCOM subscription services. The Contractor shall identify authorized network infrastructure for the ordering activity. In some cases, the user of the terminal may access network infrastructure owned or operated by a third party. In the event a terminal is used on a third party's network infrastructure, the Contractor shall provide to the ordering activity, invoices and documentation reflecting actual usage amount and third party charges incurred. The ordering activity shall be billed the actual third party charges incurred, or the contract third party billing price, whichever is less.

(End of clause)

**552.238-132 Environmental Protection Agency Registration Requirement.**

As prescribed in 538.273(d)(43), insert the following clause:

**Environmental Protection Agency Registration Requirement (Date)**

(a) With respect to the products described in this solicitation which require registration with the Environmental Protection Agency (EPA), as required by the Federal Insecticide, Fungicide, and Rodenticide Act, Section 3, Registration of Pesticides, awards will be made only for such products that have been assigned an EPA registration number, prior to the time of bid opening.

(b) The offeror shall insert in the spaces provided below, the manufacturer's and/or distributor's name and the "EPA Registration Number" for each item offered. Any offer which does not specify a current "EPA Registration Number" in effect for the duration of the contract period, and including the manufacturer's and/or distributor's name will be rejected.

Item Nos.	Name of manufacturer/ Distributor No.	EPA Registration	Date of expiration
_____	_____	_____	_____

(c) If, during the performance of a contract awarded as a result of this solicitation, the EPA Registration Number for products being furnished is terminated, withdrawn, canceled, or suspended, and such action does not arise out of causes beyond the control, and with the fault or negligence of the

Contractor or subcontractor, the Government may terminate the contract pursuant to either the Default Clause or Termination for Cause Paragraph (contained in the clause 52.212-4, Contract Terms and Conditions—Commercial Items), whichever is applicable to the resultant contract.

13 CFR Part 121

Small Business Size Standards for Manufacturing; Proposed Rule

**SMALL BUSINESS ADMINISTRATION****13 CFR Part 121**

RIN 3245-AG50

**Small Business Size Standards for Manufacturing**

AGENCY: U.S. Small Business Administration.

ACTION: Proposed rule.

**SUMMARY:** The U.S. Small Business Administration (SBA) proposes to increase small business size standards for 209 industries in North American Industry Classification System (NAICS) Sector 31-33, Manufacturing. SBA also proposes to increase the refining capacity component of the Petroleum Refiners (NAICS 324110) size standard to 200,000 barrels per calendar day total capacity for businesses that are primarily engaged in petroleum refining. In addition, SBA proposes to eliminate the requirement that 90 percent of output being delivered is refined by the bidder. As part of its ongoing comprehensive size standards review, SBA evaluated employee based size standards for all 364 industries in NAICS Sector 31-33 to determine whether they should be retained or revised. This proposed rule is one of a series of proposed rules that will review size standards of industries grouped by NAICS Sector.

**DATES:** SBA must receive comments to this proposed rule on or before November 10, 2014.

**ADDRESSES:** Identify your comments by RIN 3245-AG50 and submit them by one of the following methods:

(1) *Federal eRulemaking Portal:* [www.regulations.gov](http://www.regulations.gov), following the instructions for submitting comments; or

(2) *Mail/Hand Delivery/Courier:* Khem R. Sharma, Ph.D., Chief, Size Standards Division, 409 Third Street SW., Mail Code 6530, Washington, DC 20416. SBA will not accept comments to this proposed rule submitted by email.

SBA will post all comments to this proposed rule on [www.regulations.gov](http://www.regulations.gov). If you wish to submit confidential business information (CBI) as defined in the User Notice at [www.regulations.gov](http://www.regulations.gov), you must submit such information to U.S. Small Business Administration, Khem R. Sharma, Ph.D., Chief, Size Standards Division, 409 Third Street SW., Mail Code 6530, Washington, DC 20416, or send an email to [sizestandards@sba.gov](mailto:sizestandards@sba.gov). Highlight the information that you consider to be CBI and explain why you believe SBA should hold this information as

confidential. SBA will review your information and determine whether it will make the information public.

**FOR FURTHER INFORMATION CONTACT:** Jorge Laboy-Bruno, Ph.D., Economist, Size Standards Division, (202) 205-6618 or [sizestandards@sba.gov](mailto:sizestandards@sba.gov).

**SUPPLEMENTARY INFORMATION:** To determine eligibility for Federal small business assistance, SBA establishes small business size definitions (referred to as size standards) for private sector industries in the United States. SBA uses two primary measures of business size—average annual receipts and average number of employees. SBA uses financial assets, electric output, and refining capacity to measure the size of a few specialized industries. In addition, SBA's Small Business Investment Company (SBIC), Certified Development Company (504), and 7(a) Loan Programs use either the industry based size standards, or net worth and net income based alternative size standards to determine eligibility for those programs. At the start of the SBA's current comprehensive size standards review when the size standards were based on NAICS 2007, there were 41 different size standards covering 1,141 NAICS industries and 18 sub-industry activities ("exceptions" in SBA's table of size standards). Thirty-one of these size levels were based on average annual receipts, seven were based on average number of employees, and three were based on other measures. Presently, under NAICS 2012, there are 28 different size standards covering 1,031 industries and 16 "exceptions". Of these, 533 are based on average annual receipts, 509 on number of employees (one of which also contains barrels per day total capacity), and five on average assets.

Over the years, SBA has received comments that its size standards have not kept up with changes in the economy, in particular the changes in the Federal contracting marketplace and industry structure. The last time SBA conducted a comprehensive size standards review was during the late 1970s and early 1980s. Since then, most reviews of size standards were limited to a few specific industries, mostly with receipts based size standards, in response to requests from the public and Federal agencies. SBA reviews all monetary based size standards (except for statutorily set size standards in NAICS Sector 11) for inflation at least once every five years. SBA's latest inflation adjustment to size standards was published in the **Federal Register** on June 12, 2014 (79 FR 33647). However, the vast majority of

manufacturing size standards have not been reviewed since they were first established.

Because of changes in the Federal marketplace and industry structure since the last comprehensive size standards review, SBA recognizes that current data may no longer support some of its existing size standards. Accordingly, in 2007, SBA began a comprehensive size standards review to determine if they are consistent with current data, and to adjust them when necessary. In addition, on September 27, 2010, the President of the United States signed the Small Business Jobs Act of 2010 (Jobs Act). The Jobs Act directs SBA to conduct a detailed review of all size standards and to make appropriate adjustments to reflect market conditions. Specifically, the Jobs Act requires SBA to conduct a detailed review of at least one-third of all size standards during every 18-month period from the date of its enactment. In addition, the Jobs Act requires that SBA review all size standards not less frequently than once every five years thereafter. Reviewing existing small business size standards and making appropriate adjustments based on the latest available data are also consistent with Executive Order 13563 on improving regulation and regulatory review.

Rather than review all size standards at one time, SBA is reviewing size standards on a Sector by Sector basis. A NAICS Sector generally includes 25 to 75 industries, except for NAICS Sector 31-33, Manufacturing, which has more than 350 industries. As stated above, this proposed rule covers all industries in NAICS Sector 31-33. Once SBA completes its review of size standards for industries in a NAICS Sector, it issues a proposed rule to revise size standards for those industries based on latest industry and program data available and other relevant factors, such as current economic climate and SBA's and other government's programs and policies to help small businesses.

Below is a discussion of SBA's size standards methodology for establishing employee based size standards that the Agency applied to this proposed rule, including analyses of industry structure, Federal contracting factor, the impact of the proposed revisions to size standards on SBA's financial assistance to small businesses, and the evaluation of whether a revised size standard would exclude dominant firms from being considered small.

**Size Standards Methodology**

In conjunction with the current comprehensive size standards review,

SBA developed a “Size Standards Methodology” for developing, reviewing, and modifying size standards when necessary. SBA published the document on its Web site at [www.sba.gov/size](http://www.sba.gov/size) for public review and comments, and has included it as a supporting document in the electronic docket of this proposed rule at [www.regulations.gov](http://www.regulations.gov). It should be noted that SBA does not apply all features of its “Size Standards Methodology” to all industries because not all features are appropriate for every industry. For example, since all industries in Sector 31–33 have employee based size standards, the methodology described in this proposed rule relates only to establishing employee based size standards. However, the methodology is available in its entirety for parties who have an interest in SBA’s overall approach to establishing, evaluating, and modifying small business size standards. SBA always explains its methodology and analysis in individual proposed and final rules relating to size standards for specific industries.

SBA welcomes comments from the public on a number of issues concerning its “Size Standards Methodology,” that the Agency has applied in this proposed rule, such as whether there are other approaches to establishing and modifying size standards; whether there are alternative or additional factors that SBA should consider; whether SBA’s approach to small business size standards makes sense in the current economic environment; whether SBA’s use of anchor size standards is appropriate; whether there are gaps in SBA’s methodology because the data it uses are not current or sufficiently comprehensive; and whether there are other data, facts, and/or issues that SBA should consider. Comments on SBA’s size standards methodology should be submitted via: (1) The Federal eRulemaking Portal:

[www.regulations.gov](http://www.regulations.gov), following the instructions for submitting comments; the docket number is SBA–2009–0008, or (2) Mail/Hand Delivery/Courier: Khem R. Sharma, Ph.D., Chief, Size Standards Division, 409 Third Street SW., Mail Code 6530, Washington, DC 20416. As it will do with comments to this and other proposed rules, SBA will post all comments on its methodology on [www.regulations.gov](http://www.regulations.gov). As of June 12, 2014, SBA has received 18 comments to its “Size Standards Methodology.” The comments are available to the public at [www.regulations.gov](http://www.regulations.gov). SBA continues to welcome comments on its methodology from interested parties. SBA will not

accept comments to its “Size Standards Methodology” submitted by email.

Congress granted the SBA’s Administrator discretion to establish detailed small business size standards. 15 U.S.C. 632(a)(2). Specifically, Section 3(a)(3) of the Small Business Act (15 U.S.C. 632(a)(3)) requires that “. . . the [SBA] Administrator shall ensure that the size standard varies from industry to industry to the extent necessary to reflect the differing characteristics of the various industries and consider other factors deemed to be relevant by the Administrator.” Accordingly, the economic structure of an industry is the basis for developing and modifying small business size standards. SBA identifies the small business segment of an industry by examining data on the economic characteristics defining the industry structure (as described below). In addition, SBA considers current economic conditions, its mission and program objectives, the Administration’s current policies, suggestions from industry groups and Federal agencies, and public comments on the proposed rule. SBA also examines whether a size standard based on industry and other relevant data successfully excludes businesses that are dominant in the industry.

This proposed rule includes information regarding the factors SBA evaluated and the criteria it used to propose adjustments, where necessary, to size standards for industries covered by this rule. This proposed rule affords the public an opportunity to review and to comment on SBA’s proposal to revise size standards for certain industries, as well as on the data and methodology it used to evaluate and revise the size standards.

#### Industry Analysis

For the current comprehensive size standards review, SBA has established three “base” or “anchor” size standards—\$7.0 million in average annual receipts for industries that have receipts based size standards, 500 employees for Manufacturing and industries that have employee based size standards in non-manufacturing Sectors (except for Wholesale Trade and Retail Trade), and 100 employees for industries in the Wholesale and Retail Trade Sectors that have employee based size standards. SBA established 500 employees as the anchor size standard for manufacturing industries at its inception in 1953. Shortly thereafter, SBA established \$1 million in average annual receipts as the anchor size standard for nonmanufacturing industries. SBA has periodically increased the receipts based anchor size

standard for inflation, and today it is \$7 million. Since 1986, the size standard for all industries in the Wholesale Trade Sector for SBA’s financial assistance and for most Federal programs has been 100 employees. Presently, SBA also has employee based size standards for two industries in Retail Trade, namely NAICS 441110, New Car Dealers (200 employees) and NAICS 454310, Fuel Dealers (50 employees). However, NAICS codes for the Wholesale and Retail Trade Sectors and their size standards do not apply to Federal procurement programs. Rather, for Federal procurement the size standard for all industries in Wholesale Trade (NAICS Sector 42) and for all industries in Retail Trade (NAICS Sector 44–45) is 500 employees under the SBA’s nonmanufacturer rule (13 CFR 121.406(b)).

These long-standing anchor size standards have stood the test of time and gained legitimacy through practice and general public acceptance. An anchor is neither a minimum nor a maximum size standard. It is a common size standard for a large number of industries that have similar economic characteristics and serves as a reference point in evaluating size standards for individual industries. SBA uses the anchor in lieu of trying to establish precise small business size standards for each industry. Otherwise, theoretically, the number of size standards might be as high as the number of industries for which SBA establishes size standards (i.e., more than 1,000). Furthermore, the data SBA analyzes are static, while the U.S. economy is not. Hence, absolute precision is impossible. Similarly, because of the disclosure problem in getting the distribution of firms by more granular size classes, the 2007 Economic Census tabulation (the latest available when this proposed rule was prepared) that SBA received from the U.S. Census Bureau for current size standards review would not allow an accurate regulatory impact analysis of size standards changes if precise, separate size standards were established for each industry. SBA presumes an anchor size standard is appropriate for a particular industry unless that industry displays economic characteristics that are considerably different from other industries with the same anchor size standard.

When evaluating a size standard, SBA compares the economic characteristics of the industry under review to the average characteristics of industries with one of the three anchor size standards (referred to as the “anchor comparison group”). This allows SBA to assess the industry structure and to

determine whether the industry is appreciably different from the other industries in the anchor comparison group. If the characteristics of a specific industry under review are similar to the average characteristics of the anchor comparison group, the anchor size standard is generally appropriate for that industry. SBA may consider adopting a size standard below the anchor when: (1) All or most of the industry characteristics are significantly smaller than the average characteristics of the anchor comparison group; or (2) other industry considerations strongly suggest that the anchor size standard would be an unreasonably high size standard for the industry.

If the specific industry's characteristics are significantly higher than those of the anchor comparison group, then a size standard higher than the anchor size standard may be appropriate. The larger the differences are between the characteristics of the industry under review and those in the anchor comparison group, the larger will be the difference between the appropriate industry size standard and the anchor size standard. To determine a size standard above the anchor size standard, SBA analyzes the characteristics of a second comparison group.

For industries with employee based size standards in manufacturing and industries not in Sector 42 (Wholesale Trade) or Sector 44–45 (Retail Trade), SBA has developed a second comparison group consisting of industries that have the highest of employee based size standards. To determine a size standard above the 500-employee anchor size standard, SBA analyzes the characteristics of this second comparison group. The industries in this group have size standards of either 1,000 employees or 1,500 employees; the weighted average size standard for the group is 1,323 employees. SBA refers to this comparison group as the "higher level employee based size standard group."

To examine industry structure, SBA evaluates average firm size, startup costs and entry barriers, industry competition, and distribution of firms by size. SBA also evaluates the level and small business share of total Federal contracting dollars. These are, generally, the five primary factors SBA examines when establishing or revising a size standard for an industry. However, SBA will also consider and evaluate other information that it believes is relevant to a particular industry (such as technological changes, growth trends, SBA financial assistance, other program factors, etc.). SBA also considers

possible impacts of size standard revisions on eligibility for Federal small business assistance, current economic conditions, the Administration's policies, and suggestions from industry groups and Federal agencies. Public comments on a proposed rule also provide important additional information. SBA thoroughly reviews all public comments before making a final decision on its proposed size standards. Below are brief descriptions of each of the five primary factors that SBA has evaluated for each industry and sub-industry covered by this proposed rule. A more detailed description of these factors is provided in SBA's "Size Standards Methodology," available at <http://www.sba.gov/size>.

1. *Average firm size.* SBA computes two measures of average firm size: Simple average and weighted average. For industries with employee based size standards, the simple average firm size is the total number of employees in an industry divided by the total number of firms in that industry. The weighted average firm size is the sum of weighted simple average firm sizes in different employee size classes, where weights are the shares of total industry employees for respective employee size classes. The simple average firm size weighs all firms within an industry equally regardless of their size. The weighted average firm size overcomes that limitation by giving more weight to larger firms.

If the average firm size of an industry is significantly higher than the average firm size of industries in the anchor comparison industry group, this will generally support a size standard higher than the anchor size standard. Conversely, if the industry's average firm size is similar to or significantly lower than that of the anchor comparison industry group, it will be a basis to adopt the anchor size standard, or, in rare cases, a standard lower than the anchor.

2. *Startup costs and entry barriers.* Startup costs reflect a firm's initial size in an industry. New entrants to an industry must have sufficient capital and other assets to start and maintain a viable business. If new firms entering a particular industry have greater capital requirements than firms in industries in the anchor comparison group, this can be a basis for establishing a size standard higher than the anchor size standard. In lieu of actual startup cost data, SBA uses average assets as a proxy to measure the capital requirements for new entrants to an industry.

To calculate average assets, SBA begins with the sales to total assets ratio for an industry from the Risk

Management Association's Annual eStatement Studies. SBA then applies these ratios to the average receipts of firms in that industry. An industry with average assets that are significantly higher than those of the anchor comparison group is likely to have higher startup costs; this in turn will support a size standard higher than the anchor. Conversely, an industry with average assets that are similar to or lower than those of the anchor comparison group is likely to have lower startup costs; this will support the anchor standard or one lower than the anchor.

3. *Industry competition.* Industry competition is generally measured by the share of total industry receipts generated by the largest firms in an industry. SBA generally evaluates the share of industry receipts generated by the four largest firms in each industry. This is referred to as the "four-firm concentration ratio," a commonly used economic measure of market competition. If a significant share of economic activity within the industry is concentrated among a few relatively large companies, all else being equal, SBA will establish a size standard higher than the anchor size standard. SBA does not consider the four-firm concentration ratio as an important factor in assessing a size standard if its share of economic activity of the largest four firms within the industry is less than 40 percent. For an industry with a four-firm concentration ratio of 40 percent or more, SBA compares the average employee size of the four largest firms in the industry with the average employee size of the four largest firms in the anchor and higher level size comparison groups to determine an employee size standard for that industry.

4. *Distribution of firms by size.* For employee based size standards, SBA examines the shares of industry total receipts accounted for by firms of various employment size classes in an industry. This is an additional factor SBA examines in assessing industry competition. If most of an industry's economic activity is attributable to smaller firms, this generally indicates that small businesses are competitive in that industry. This can, generally, support adopting the anchor size standard. If most of an industry's economic activity is attributable to larger firms, this indicates that small businesses are not competitive in that industry. This can support adopting a size standard above the anchor.

Concentration is a measure of inequality of distribution. To determine the degree of inequality of distribution

in an industry, SBA computes the Gini coefficient by constructing the Lorenz curve. The Lorenz curve presents the cumulative percentages of units (firms) in various employee size classes along the horizontal axis and the cumulative percentages of receipts (or other measures of size) in the same employee size classes along the vertical axis. (For further detail, please refer to SBA's "Size Standards Methodology" on its Web site at [www.sba.gov/size](http://www.sba.gov/size).) Gini coefficient values vary from zero to one. If receipts are distributed equally among all the firms in an industry, the value of the Gini coefficient will equal zero. If an industry's total receipts are attributed to a single firm, the Gini coefficient will equal one.

SBA compares the Gini coefficient value for an industry with that for industries in the anchor comparison group. If the Gini coefficient value for an industry is higher than it is for industries in the anchor comparison industry group this may, all else being equal, warrant a size standard higher than the anchor. Conversely, if an industry's Gini coefficient is similar to or lower than that for the anchor group, the anchor standard, or in some cases a standard lower than the anchor, may be adopted.

**5. Impact on Federal contracting and SBA loan programs.** SBA examines the possible impact a size standard change may have on Federal small business assistance. This most often focuses on the level and small business share of total Federal contracting dollars in the industry in question. In general, if the small business share of total Federal contracting dollars in an industry with significant Federal contracting is appreciably less than the small business share of the industry's total receipts, this could justify considering a size standard higher than the existing size standard. If the small business share of an industry's total Federal contracting dollars is similar to or higher than the small business share of its total receipts, this would support the existing size standard for that industry. By comparing the small business share in the Federal market with the small business share in the industry-wide market, SBA accounts for conditions in the Federal market in its size standards analysis. The disparity between the small business Federal market share and small business industry-wide share may be due to various factors, such as extensive administrative and compliance requirements associated with Federal contracts, the different skill set required for Federal contracts as compared to typical commercial contracting work, and the size of

Federal contracts. Data permitting, SBA will also examine these, as well as other factors that are likely to influence the type of firms within an industry that compete for Federal contracts.

SBA considers the Federal contracting factor in an industry's size standards analysis only if the industry's total Federal contracting dollars average \$100 million or more annually during the latest three fiscal years. SBA believes that this threshold reflects a significant level of contracting where a revision to a size standard may have an impact on contracting opportunities to small businesses. For industries where total contracting dollars average \$100 million or more annually, SBA establishes a size standard higher than the existing size standard if the small business share of total industry receipts is 10 percent or higher than the small business share of total industry receipts. If this difference is less than 10 percent, this would support the existing size standard.

Besides the impact on small business Federal contracting, SBA also evaluates the impact of a proposed size standard revision on SBA's loan programs. For this, SBA examines the data on volume and number of its guaranteed loans within an industry and the size of firms obtaining those loans. This allows SBA to assess whether the existing, proposed, or revised size standard for a particular industry may restrict the level of financial assistance to small firms. If existing size standards are found to have impeded financial assistance to small businesses, higher size standards may be justified. However, if small businesses under existing size standards have been receiving significant amounts of financial assistance through SBA's loan programs, or if the financial assistance has been provided mainly to businesses that are much smaller than the existing size standards, SBA does not consider this factor when determining the size standard.

#### Sources of Industry and Program Data

SBA's primary source of industry data used in this proposed rule is a special tabulation of the 2007 Economic Census (see [www.census.gov/econ/census07/](http://www.census.gov/econ/census07/)) prepared by the U.S. Bureau of the Census (Census Bureau) for SBA. The 2007 Economic Census data are the latest Economic Census data available at the time of drafting this proposed rule. SBA expects to receive the special tabulation from the 2012 Economic Census in 2016 for the next round of comprehensive size standards review. The special tabulation provides SBA with data on the number of firms, number of establishments, number of employees, annual payroll, and annual

receipts of companies by Industry (6-digit level), Industry Group (4-digit level), Subsector (3-digit level), and Sector (2-digit level). These data are arrayed by various classes of firms' size based on the overall number of employees and receipts of the entire enterprise (all establishments and affiliated firms) from all industries. The special tabulation enables SBA to evaluate average firm size, the four-firm concentration ratio, and distribution of firms by various receipts and employment size classes. It should be noted that the Economic Census tabulation data on the number of firms, number of establishments, number of employees, annual payroll, and annual receipts for a particular NAICS Industry category relate to establishments and firms that are primarily engaged in that Industry. To mitigate this limitation of the Economic Census tabulation data, SBA also examines the data from the System of Award Management (SAM) (formerly Central Contractor Registration (CCR)) and FPDS-NG which provides more recent data on Federal contract awards by NAICS code and the actual size of the concerns receiving the contract awards.

In some cases, where data were not available at the 6-digit industry level due to disclosure prohibitions in the Census Bureau's tabulation, SBA either estimates missing values using available relevant data or examines data at a higher level of industry aggregation, such as at the NAICS 2-digit (Sector), 3-digit (Subsector), or 4-digit (Industry Group) level. In some instances, SBA's analysis is based only on those factors for which data are available or estimates of missing values are possible.

To evaluate the refining capacity component of the size standard for NAICS 324110, Petroleum Refiners, SBA evaluated a special tabulation of refinery production data obtained from Energy Information Administration (EIA). SBA obtained the data on number of employees for petroleum refining companies in the EIA tabulation from Duns and Bradstreet ([www.dnb.com](http://www.dnb.com)) and those companies' SAM (CCR) profiles.

To calculate average assets, SBA used sales to total assets ratios from the Risk Management Association's Annual eStatement Studies, 2009–2011, available at [www.statementstudies.org](http://www.statementstudies.org).

To evaluate the Federal contracting factor, SBA examined the data from FPDS-NG for fiscal years 2009–2011, available at <https://www.fpds.gov> and 2007 Economic Census tabulation, which is the latest available as stated elsewhere in the rule.

To assess the impact on financial assistance to small businesses, SBA examined its internal data on 7(a) and 504 loan programs for fiscal years 2010–2012.

Data sources and estimation procedures SBA uses in its size standards analysis are documented in detail in SBA's "Size Standards Methodology" White Paper, which is available at [www.sba.gov/size](http://www.sba.gov/size).

### Dominance in Field of Operation

Section 3(a) of the Small Business Act (15 U.S.C. 632(a)) defines a small business concern as one that: (1) Is independently owned and operated; (2) is not dominant in its field of operation; and (3) meets a specific small business definition or size standard established by SBA's Administrator. SBA considers as part of its evaluation whether a business concern at a proposed or revised size standard would be dominant in its field of operation. For this, SBA generally examines the industry's market share of firms at the proposed or revised standard. SBA also examines distribution of firms by size to ensure that a contemplated size standard derived from its size standards analysis excludes the largest firms within an industry. Market share, the size distribution and other factors may indicate whether a firm can exercise a major controlling influence on a national basis in an industry where a significant number of business concerns are engaged. If a contemplated size standard includes dominant or the largest firms in an industry, SBA will consider a lower size standard than the one suggested by the analytical results to exclude the dominant and largest firms from being defined as small.

### Selection of Size Standards

In NAICS Sector 31–33 (Manufacturing), currently there are four levels of employee based size standards: 500 employees (minimum), 750 employees, 1,000 employees, and 1,500 employees (maximum). In this proposed rule, SBA has applied its "Size Standards Methodology" for employee based size standards with two modifications. First, to be consistent with its policy of not lowering any size standards in all recent proposed and final rules on receipts based size standards, SBA is retaining the current 500-employee minimum and 1,500-employee maximum size standards for all industries in the Manufacturing

Sector. In its "Size Standards Methodology," SBA had proposed setting the minimum size standard for manufacturing industries at 250 employees and the maximum size standard at 1,000 employees. However, doing so would mean lowering existing size standards, thereby making currently small businesses ineligible to continue their participation in Federal small business programs. This would run counter to what SBA and the Administration are doing to help small businesses to create jobs and boost economic growth. Further, lowering a manufacturing size standard below 500 employees would conflict with the existing 500-employee size standard for non-manufacturers under the SBA's non-manufacturer's rule. Second, SBA is proposing a new 1,250-employee size standard between 1,000 employees and 1,500 employees. This new size standard level maintains the same 250-employee increment between the two successive levels that SBA has below 1,000 employees (500, 750, 1,000). SBA proposes, therefore, to apply one of these five employee based size standards to the analysis of size standards for industries in the Manufacturing Sector: 500 employees, 750 employees, 1,000 employees, 1,250 employees, and 1,500 employees.

To simplify size standards and for other reasons, SBA may propose a common size standard for closely related industries. Although the size standard analysis may support a separate size standard for each industry, SBA believes that establishing different size standards for closely related industries may not always be appropriate. For example, in cases where many of the same businesses operate in the same multiple industries, a common size standard for those industries might better reflect the Federal marketplace. This might also make size standards among related industries more consistent than separate size standards for each of those industries. Whenever SBA proposes a common size standard for closely related industries it will provide its justification.

### Evaluation of Industry Structure

In this proposed rule, SBA evaluated 364 industries in NAICS Sectors 31–33 to assess the appropriateness of their current size standards. As described above, SBA compared data on the economic characteristics of each of

those industries to the average characteristics of industries in two comparison groups. The first comparison group consists of all industries in Manufacturing and industries not in Wholesale Trade or Retail Trade with 500-employee size standards. SBA refers this group of industries to as the "employee based anchor comparison group." Because the goal of SBA's review is to assess whether a specific industry's size standard should be the same as or different from the anchor size standard, this is the most logical group of industries to analyze. In addition, this group includes a sufficient number of firms to provide a meaningful assessment and comparison of industry characteristics.

As stated previously, if the characteristics of an industry are similar to the average characteristics of industries in the anchor comparison group, the anchor size standard is generally appropriate for that industry. If an industry's structure is significantly different from industries in the anchor group, a size standard lower or higher than the anchor size standard might be appropriate. The proposed new size standard is based on the difference between the characteristics of the anchor comparison group and a second industry comparison group. As described above, the second comparison group for employee based standards consists of industries with either 1,000-employee or 1,500-employee size standards. The weighted average size standard for this group is 1,323 employees. SBA refers this group of industries to as the "higher level employee based size standard comparison group." SBA determines differences in industry structure between an industry under review and the industries in the two comparison groups by comparing data on each of the industry factors, including average firm size, average assets size, the four-firm concentration ratio, and the Gini coefficient of distribution of firms by size. Table 1, Average Characteristics of Employee Based Comparison Groups, shows the average firm size (both simple and weighted), average assets size, four-firm concentration ratio, average employees of the four largest firms, and the Gini coefficient for both anchor level and higher level comparison groups for employee based size standards.

TABLE 1—AVERAGE CHARACTERISTICS OF EMPLOYEE BASED COMPARISON GROUPS

Employee based comparison group	Average firm size (number of employees)		Average assets size (\$ million)	Four-firm concentration ratio (%)	Average employees of four largest firms <sup>*</sup>	Gini coefficient
	Simple average	Weighted average				
Anchor Level .....	51	322	\$6.4	35.9	1,267	0.765
Higher Level .....	136	602	37.0	64.3	2,033	0.808

\* To be used for industries with a four-firm concentration ratio of 40% or greater.

**Derivation of Size Standards Based on Industry Factors**

For each industry factor in Table 1, Average Characteristics of Employee Based Comparison Groups, SBA derives a separate size standard based on the differences between the values for an industry under review and the values for the two comparison groups. If the industry value for a particular factor is near the corresponding factor for the anchor comparison group, the 500-employee anchor size standard is appropriate for that factor.

An industry factor significantly above or below the anchor comparison group will generally imply a size standard for that industry above or below the 500-employee anchor. The new size standard in these cases is based on the proportional difference between the industry value and the values for the two comparison groups.

For example, an industry’s simple average firm size of 75 employees will

support a 750-employee size standard. The 75-employee level is 28.2 percent between 51 employees for the anchor comparison group and 136 employees for the higher level comparison group ((75 employees – 51 employees) ÷ (136 employees – 51 employees) = 0.282 or 28.2%). This proportional difference is applied to the difference between the size standard of 500 employees for the anchor level size standard group and average size standard of 1,323 employees for the higher level size standard group and then added to 500 employees to estimate a size standard of 733 employees ((1,323 employees – 500 employees) \* 0.282) + 500 employees = 733 employees). The final step is to round the estimated 733-employee size standard to the nearest size standard level, which in this example is 750 employees.

SBA applies the above calculation to derive a size standard for each industry factor. Detailed formulas involved in

these calculations are presented in SBA’s “Size Standards Methodology” which is available on its Web site at [www.sba.gov/size](http://www.sba.gov/size). As stated above, SBA has also included its “Size Standards Methodology” as a supporting document in the electronic docket of this proposed rule at [www.regulations.gov](http://www.regulations.gov). (However, it should be noted that figures in the “Size Standards Methodology” White Paper are based on 2002 Economic Census data and are different from those presented in this proposed rule. That is because when SBA prepared its “Size Standards Methodology,” the 2007 Economic Census data were not yet available). Table 2, Values of Industry Factors and Supported Size Standards, below, shows ranges of values for each industry factor and the levels of size standards supported by those values.

TABLE 2—VALUES OF INDUSTRY FACTORS AND SUPPORTED SIZE STANDARDS

If simple average firm size (number of employees)	Or if weighted average firm size (number of employees)	Or if average assets size (\$ million)	Or if average number employees of largest four firms	Or if Gini coefficient	Then implied size standard is (number of employees)
< 63.9 .....	< 364.5 .....	< 11.1 .....	< 1,383.3 .....	< 0.772 .....	500
63.9 to < 89.7 .....	364.5 to < 449.6 .....	11.1 to < 20.3 .....	1,383.3 to < 1,616.0 .....	0.772 to < 0.785 .....	750
89.7 to < 115.6 .....	449.6 to < 534.6 .....	20.3 to < 29.6 .....	1,616.0 to < 1,848.7 .....	0.785 to < 0.798 .....	1,000
115.6 to < 141.4 .....	534.6 to < 619.7 .....	29.6 to < 38.9 .....	1,848.7 to < 2,081.4 .....	0.798 to < 0.811 .....	1,250
≥ 141.4 .....	≥ 619.7 .....	≥ 38.9 .....	≥ 2,081.4 .....	≥ 0.811 .....	1,500

**Derivation of Size Standard Based on Federal Contracting Factor**

Besides industry structure, SBA also evaluates Federal contracting data to assess the success of small businesses in getting Federal contracts under the existing size standards. For industries where Federal contract dollars average \$100 million or more annually and the small business share of total Federal contracting dollars is 10 to 30 percent lower than the small business share of total industry receipts, SBA has designated a size standard one level higher than their current size standard. For industries where the small business share of total Federal contracting dollars

is more than 30 percent lower than the small business share of total industry receipts, SBA has designated a size standard two levels higher than the current size standard. For industries, where this difference is less than 10 percent, SBA applies the existing size standard for the Federal contracting factor.

Because of the complex relationships among several variables affecting small business participation in the Federal marketplace, SBA has chosen not to designate a size standard for the Federal contracting factor alone that is more than two levels above the current size standard. SBA believes that a larger

adjustment to size standards based on Federal contracting activity should be based on a more detailed analysis of the impact of any subsequent revision to the current size standard. In limited situations, however, SBA may conduct a more extensive examination of Federal contracting experience. This may support a different size standard than indicated by this general rule and take into consideration significant and unique aspects of small business competitiveness in the Federal contract market. SBA welcomes comments on its methodology for incorporating the Federal contracting factor in its size standard analysis and suggestions for

alternative methods and other relevant information on small business experience in the Federal contract market that SBA should consider.

When SBA adopted NAICS 2012 for its size standards, a number of industries under NAICS 2007 were merged to form new industries or combined with other existing industries. SBA adopted the highest size standard among the merged or combined industries under NAICS 2007 as the size standard for the new industry or modified industry under NAICS 2012. As a result, the size standard increased, effective October 1, 2012, for a number of industries in NAICS Sector 31–33. However, FPDS-NG data for fiscal years 2009–2011 that SBA analyzed to derive the Federal contracting factor were based on older size standards under NAICS 2007. Thus, for industries for which the size standard increased due to the adoption of NAICS 2012, the Federal contracting factor was based on the size standard that was on effect prior to October 1, 2012. Similarly, where multiple industries were merged to a new, single industry, the size standard for Federal contract factor for the new industry was the weighted average size standard of the merged industries prior to October 1, 2012, rounded to the

nearest size level. The shares of contract dollars of individual merged industries served as the weights in computing the weighted average size standard.

Of the 364 industries reviewed in this proposed rule, 119 averaged \$100 million or more annually in Federal contracting during fiscal years 2009–2011 and thus, the Federal contracting factor was significant for those industries. Of the 119 industries, the difference between the small business share of total industry receipts and small business share of Federal contracting dollars was less than 10 percent for 78 industries and in this proposed rule, SBA applied the existing size standard to each. This difference was between 10 and 30 percent for 29 industries for which a size standard one level higher than the existing size standard was applied. Finally, in 12 industries, this difference was more than 30 percent and a size standard that was two levels higher than the existing size standard was applied.

**New Size Standards Based on Industry and Federal Contracting Factors**

Table 3, Size Standards Supported by Each Factor for Each Industry (No. of Employees), below, shows the results of analyses of industry and Federal

contracting factors for each industry covered by this proposed rule. Many NAICS industries in columns 2, 3, 4, 6, and 7 show two numbers. The upper number is the value for the industry factor shown on the top of the column and the lower number is the size standard supported by that factor. For the four-firm concentration ratio, SBA estimates a size standard only if its value is 40 percent or more. If the four-firm concentration ratio for an industry is less than 40 percent, SBA does not estimate a size standard for that factor. If the four-firm concentration ratio is 40 percent or more, SBA indicates in column 6 the average size of the industry’s four largest firms together with a size standard based on that average. Column 9 shows a calculated new size standard for each industry. This is the average of the size standards supported by each factor, rounded to the nearest fixed size level. However, the size standards for the simple average and weighted average firm size are averaged together, and therefore receive a single weight. Analytical details involved in the averaging procedure are described in SBA’s “Size Standard Methodology.” For comparison with the new standards, the current size standards are in column 10 of Table 3.

**TABLE 3—SIZE STANDARDS SUPPORTED BY EACH FACTOR FOR EACH INDUSTRY (NUMBER OF EMPLOYEES)**  
 [Upper Value = Calculated Factor, Lower Value = Size Standard Supported]

NAICS code NAICS industry title	Simple average firm size (number of employ- ees)	Weighted average firm size (number of employ- ees)	Average assets size (\$ million)	Four-firm ratio %	Four-firm average size (number of employ- ees)	Gini coefficient	Federal contract factor (%)	Calculated size standard (number of employ- ees)	Current size standard (number of employ- ees)

**Special Considerations: NAICS Code 324110 (Petroleum Refiners)**

Footnote 4 of SBA's table of size standards (13 CFR 121.201) states that to

qualify as a small business concern for purposes of Government procurement, the petroleum refiner must be a concern that has no more than 1,500 employees and no more than 125,000 barrels per

calendar day total Operable Atmospheric Crude Oil Distillation capacity. In addition, the total product to be delivered under the small business contract must be at least 90 percent

refined by the successful bidder from either crude oil or bona fide feedstocks.

To determine if the current Petroleum Refiners size standard is appropriate, SBA analyzed current data on both total and aviation fuel capacity, as well as the number of employees of all refiners operating in the U.S. SBA also examined industry trends, and the Federal government's petroleum procurement needs. Based on this analysis, SBA proposes to increase the refining capacity component of the Petroleum Refiners (NAICS 324110) size standard from 125,000 barrels per calendar day (BPCD) total Operable Atmospheric Crude Oil Distillation capacity to 200,000 BPCD, and maintain the employee component at the current 1,500-employee level. Under the proposed size standard, for purposes of Federal procurement, a petroleum refiner can qualify as small under the 1,500-employee size standard or under the 200,000 BPCD capacity size standard. To qualify under the capacity size standard, the firm, together with its affiliates, must be primarily engaged in refining crude petroleum into refined petroleum products. The proposed increase to the capacity size standard would expand the pool of small refiners that produce aviation fuel.

Since the current regulation (limitations on subcontracting) already requires that a concern must perform at least 50 percent of the cost of contracts for the supplies or products (not including the costs of materials) (see 13 CFR 125.6), SBA is also proposing to remove the requirement that total product to be delivered under the small business contract must be at least 90 percent refined by the successful bidder from either crude oil or bona fide feedstocks. SBA has found this 90 percent requirement to be overly restrictive for small refiners to compete for government contracts. The removal of this requirement will make the limitations on subcontracting consistent across all contracts for manufactured products or supplies.

Given these changes, SBA also proposes to revise Footnote 4 of the SBA's table of size standards to read as follows:

"To qualify as small for purposes of Government procurement, the petroleum refiner, including its affiliates, must be a concern that has no more than 1,500 employees OR no more than 200,000 barrels per calendar day total Operable Atmospheric Crude Oil Distillation capacity. Capacity includes all domestic and foreign affiliates, owned or leased facilities, and facilities under a processing agreement or an arrangement such as an exchange

agreement or a throughput. To qualify under the capacity size standard, the firm, together with its affiliates, must be primarily engaged in refining crude petroleum into refined petroleum products. A firm's "primary industry" is determined in accordance with 13 CFR 121.107."

#### **NAICS 326211, Tire Manufacturing (Except Retreading)**

Footnote 5 to SBA size standards table currently includes Census Bureau's Product Classifications codes based on Standard Industry Classification (SIC) system: Namely 30111 (Passenger car pneumatic tires) and 30112 (Truck/bus tires, including off highway, pneumatic tires). To make them consistent with industry size standards that are based on NAICS, in this proposed rule, SBA amends Footnote 5 by replacing them with the Census Bureau's corresponding NAICS Product Classification codes 3262111 and 3262113, respectively. The amended Footnote 5 will read as follows:

5. *NAICS code 326211*—For Government procurement, a firm is small for bidding on a contract for pneumatic tires within Census NAICS Product Classification codes 3262111 and 3262113, provided that:

(a) The value of tires within Census NAICS Product Classification codes 3262113 which it manufactured in the United States during the previous calendar year is more than 50 percent of the value of its total worldwide manufacture,

(b) The value of pneumatic tires within Census NAICS Product Classification codes 3262113 comprising its total worldwide manufacture during the preceding calendar year was less than 5 percent of the value of all such tires manufactured in the United States during that period, and

(c) The value of the principal product which it manufactured or otherwise produced, or sold worldwide during the preceding calendar year is less than 10 percent of the total value of such products manufactured or otherwise produced or sold in the United States during that period.

#### **Proposed Changes to Size Standards**

As can be seen from Table 3, Size Standards Supported by Each Factor for Each Industry (No. of employees), the results might support increases in size standards for 209 industries, decreases for 19 industries and no changes for 136 industries.

However, SBA believes that lowering small business size standards is not in the best interest of small businesses in

the current economic environment. The U.S. economy was in recession from December 2007 to June 2009, the longest and deepest of any recessions since before World War II. The economy lost more than eight million non-farm jobs during 2008–2009. In response, Congress passed and the President signed into law the American Recovery and Reinvestment Act of 2009 (Recovery Act) to promote economic recovery and to preserve and create jobs. Although the recession officially ended in June 2009, the unemployment rate is still high at 6.2 percent in July 2014 ([www.bls.gov](http://www.bls.gov)) and is forecast to remain around this level at least through the end of 2014 ([http://www.federalreserve.gov/monetarypolicy/mpr\\_20140211\\_part3.htm](http://www.federalreserve.gov/monetarypolicy/mpr_20140211_part3.htm)).

In 2010, Congress passed and the President signed the Jobs Act to promote small business job creation. The Jobs Act puts more capital into the hands of entrepreneurs and small business owners; strengthens small businesses' ability to compete for contracts; includes recommendations from the President's Task Force on Federal Contracting Opportunities for Small Business; creates a better playing field for small businesses; promotes small business exporting, building on the President's National Export Initiative; expands training and counseling; and provides \$12 billion in tax relief to help small businesses invest in their firms and create jobs. A proposal to reduce size standards will have an immediate impact on jobs, and it would be contrary to the expressed will of the President and the Congress.

Lowering size standards would decrease the number of firms that participate in Federal financial and procurement assistance programs for small businesses. It would also affect small businesses that are now exempt or receive some form of relief from other Federal regulations that use SBA's size standards. That impact could take the form of increased fees, paperwork, or other compliance requirements for small businesses. Furthermore, size standards based solely on analytical results without any other considerations can cut off currently eligible small firms from those programs and benefits. In the 19 industries for which analytical results might have supported lowering their size standards, about 60 businesses would lose their small business eligibility if their size standards were lowered. That would run counter to what SBA and the Federal government are doing to help small businesses and create jobs. Reducing size eligibility for Federal procurement opportunities, especially under current economic

conditions, would not preserve or create more jobs; rather, it would have the opposite effect. Therefore, in this proposed rule, SBA does not intend to reduce size standards for any industries. Accordingly, for industries where analyses might seem to support lowering size standards, SBA proposes to retain the current size standards.

Furthermore, as stated previously, the Small Business Act requires the SBA's Administrator to ". . . consider other factors deemed to be relevant . . ." to establishing small business size standards. The current economic conditions and the impact on job

creation are quite relevant factors when establishing small business size standards. SBA nevertheless invites comments and suggestions on whether it should lower size standards as suggested by analyses of industry and program data or retain the current standards for those industries in view of current economic conditions.

As discussed above, lowering small business size standards is inconsistent with what the Federal government is doing to stimulate the economy and would discourage job growth for which Congress established the Recovery Act and Jobs Act. In addition, it would be

inconsistent with the Small Business Act requiring the Administrator to establish size standards based on industry analysis and other relevant factors such as current economic conditions. Thus, of the 364 manufacturing industries reviewed in this rule, SBA proposes to increase size standards for 209 industries and retain the current size standards for 155 industries, including 19 for which the results might support lowering their size standards. The proposed size standards are in Table 4, Summary of Proposed Size Standards Revisions, below.

TABLE 4—SUMMARY OF PROPOSED SIZE STANDARDS REVISIONS

NAICS code	NAICS U.S. industry title	Current size standard (number of employees)	Proposed size standard (number of employees)
311111	Dog and Cat Food Manufacturing	500	1,000
311211	Flour Milling	500	1,000
311221	Wet Corn Milling	750	1,250
311314	Cane Sugar Manufacturing	750	1,000
311340	Nonchocolate Confectionery Manufacturing	500	1,000
311351	Chocolate and Confectionery Manufacturing from Cacao Beans	500	1,250
311352	Confectionery Manufacturing from Purchased Chocolate	500	1,000
311411	Frozen Fruit, Juice, and Vegetable Manufacturing	500	1,000
311412	Frozen Specialty Food Manufacturing	500	1,250
311421	Fruit and Vegetable Canning	500	1,000
311422	Specialty Canning	1,000	1,250
311423	Dried and Dehydrated Food Manufacturing	500	750
311511	Fluid Milk Manufacturing	500	1,000
311512	Creamery Butter Manufacturing	500	750
311513	Cheese Manufacturing	500	1,250
311514	Dry, Condensed, and Evaporated Dairy Product Manufacturing	500	750
311520	Ice Cream and Frozen Dessert Manufacturing	500	1,000
311611	Animal (except Poultry) Slaughtering	500	1,000
311612	Meat Processed from Carcasses	500	1,000
311613	Rendering and Meat Byproduct Processing	500	750
311615	Poultry Processing	500	1,250
311710	Seafood Product Preparation and Packaging	500	750
311812	Commercial Bakeries	500	1,000
311813	Frozen Cakes, Pies, and Other Pastries Manufacturing	500	750
311821	Cookie and Cracker Manufacturing	750	1,250
311824	Dry Pasta, Dough, and Flour Mixes Manufacturing from Purchased Flour	500	750
311830	Tortilla Manufacturing	500	1,250
311911	Roasted Nuts and Peanut Butter Manufacturing	500	750
311919	Other Snack Food Manufacturing	500	1,250
311920	Coffee and Tea Manufacturing	500	750
311930	Flavoring Syrup and Concentrate Manufacturing	500	1,000
311941	Mayonnaise, Dressing, and Other Prepared Sauce Manufacturing	500	750
312111	Soft Drink Manufacturing	500	1,250
312112	Bottled Water Manufacturing	500	1,000
312113	Ice Manufacturing	500	750
312120	Breweries	500	1,250
312130	Wineries	500	1,000
312140	Distilleries	750	1,000
312230	Tobacco Manufacturing	1,000	1,500
313110	Fiber, Yarn, and Thread Mills	500	1,250
313230	Nonwoven Fabric Mills	500	750
314110	Carpet and Rug Mills	500	1,500
314120	Curtain and Linen Mills	500	750
315110	Hosiery and Sock Mills	500	750
315190	Other Apparel Knitting Mills	500	750
315210	Cut and Sew Apparel Contractors	500	750
315220	Men's and Boys' Cut and Sew Apparel Manufacturing	500	750
315240	Women's, Girls', and Infants' Cut and Sew Apparel Manufacturing	500	750
315280	Other Cut and Sew Apparel Manufacturing	500	750
316992	Women's Handbag and Purse Manufacturing	500	750
321212	Softwood Veneer and Plywood Manufacturing	500	1,250

TABLE 4—SUMMARY OF PROPOSED SIZE STANDARDS REVISIONS—Continued

NAICS code	NAICS U.S. industry title	Current size standard (number of employees)	Proposed size standard (number of employees)
321213	Engineered Wood Member (except Truss) Manufacturing	500	750

339993	Fastener, Button, Needle, and Pin Manufacturing	500	750
339995	Burial Casket Manufacturing	500	1,000

Maintaining current size standards when the analytical results suggested lowering them is consistent with SBA's recent final rules on NAICS Sector 44–45, Retail Trade (75 FR 61597 (October 6, 2010)); NAICS Sector 72, Accommodation and Food Services (75 FR 61604 (October 6, 2010)); NAICS Sector 81, Other Services (75 FR 61591 (October 6, 2010)); NAICS Sector 54, Professional, Scientific and Technical Services (77 FR 7490 (February 10, 2012)); NAICS Sector 48 49, Transportation and Warehousing (77 FR 10943 (February 24, 2012)); NAICS Sector 51, Information (77 FR 72702 (December 6, 2012)); NAICS Sector 53, Real Estate and Rental and Leasing (77 FR 88747 (September 24, 2012)); NAICS Sector 56, Administrative and Support, Waste Management and Remediation Services (77 FR 72691 (December 6, 2012)); NAICS Sector 61, Educational Services (77 FR 58739 (September 24, 2012)); and NAICS Sector 62, Health Care and Social Assistance (77 FR 58755 (September 24, 2012)); NAICS Sector 11, Agriculture, Forestry, Fishing and Hunting (78 FR 37398 (June 20, 2013)); NAICS Subsector 213, Support Activities for Mining (78 FR 37404 (June 20, 2013)); NAICS Sector 52, Finance and Insurance and Sector 55, Management of Companies and Enterprises (78 FR 37409 (June 20, 2013)); NAICS Sector 71, Arts, Entertainment and Recreation (78 FR 37417 (June 20, 2013)); and NAICS Sector 23, Construction (78 FR 77334

(December 23, 2013)). In each of those final rules, SBA retained the existing size standards for those that it could have reduced.

#### Evaluation of Dominance in Field of Operation

SBA has determined that for the industries for which it has proposed to increase size standards in this proposed rule, no individual firm at or below the proposed size standard will be large enough to dominate its field of operation. At the proposed size standards, if adopted, the small business share of total industry receipts among those industries for which SBA has proposed to increase their size standards is, on average, 1.7 percent, varying from a minimum of 0.02 percent to a maximum of 18.9 percent. These market shares effectively preclude a firm at or below the proposed size standards from exerting control on any of the industries.

#### Request for Comments

SBA invites public comments on this proposed rule, especially on the following issues:

1. SBA proposes five levels of employee based size standards for industries in Manufacturing and industries in other Sectors except for Wholesale Trade and Retail Trade that have employee based size standards: 500 employees, 750 employees, 1,000 employees, 1,250 employees, and 1,500 employees. SBA invites comments on

whether these proposed size levels are appropriate and suggestions on alternative levels, if they would be more appropriate.

2. To be consistent with its policy of not lowering any size standards in all recent proposed and final rules on receipts based size standards in view of current economic conditions, SBA is retaining the current 500-employee minimum and 1,500-employee maximum size standards for all industries in the Manufacturing Sector and other industries not in the Wholesale and Retail Trade Sectors that have employee based size standards. In its "Size Standards Methodology," available at [www.sba.gov/size](http://www.sba.gov/size), SBA had proposed setting the minimum size standard for these industries at 250 employees and the maximum size standard at 1,000 employees. This would have resulted in lowering the existing employee based size standards for some industries. SBA invites comments on whether it should maintain the 500-employee minimum and the 1,500-employee maximum size standards or it lower them to 250 employees and 1,000 employees, respectively, as the Agency proposed in its "Size Standards Methodology." SBA requests suggestions on alternative minimum and maximum levels, if they would be more appropriate.

3. SBA seeks feedback on whether it should adjust employee based size standards for labor productivity growth. SBA periodically increases receipts

based size standards for inflation. Should SBA take labor productivity growth and technological change into consideration when it reviews employee based standards? If so, what data are available to assist SBA in evaluating such factors? What if such an evaluation leads to lower size standards for some industries? How should SBA apply the results to its size standards decision?

4. SBA seeks feedback on whether its proposal to increase size standards for 209 industries and retain current size standards for 155 industries is appropriate, given the economic characteristics of each industry reviewed in this proposed rule. SBA also seeks feedback and suggestions on alternative size standards, if they would be more appropriate.

5. SBA has proposed to retain the current size standards for 19 industries for which the analytical results would support lowering them. SBA seeks comments on whether SBA should lower them solely based on its analysis or retain them at their current levels in view of current economic conditions.

6. SBA invites comments on its proposal to increase the capacity component of the Petroleum Refiners (NAICS 324110) size standard from 125,000 barrels per calendar day (BPCD) total Operable Atmospheric Crude Oil Distillation capacity to 200,000 BPCD and retain the employee component at the current 1,500-employee level. SBA also welcomes comments on its proposal to allow business concerns to qualify either under the 1,500-employee size standard or under the 200,000 BPCD capacity size standard, if they, together with affiliates, are primarily engaged in petroleum refining. Finally, SBA also seeks feedback on its proposal to eliminate the requirement that “[t]he total product to be delivered under the contract must be at least 90 percent refined by the successful bidder from either crude oil or bona fide feedstocks.”

7. SBA’s proposed size standards are based on five primary factors—average firm size, average assets size (as a proxy of startup costs and entry barriers), four-firm concentration ratio, distribution of firms by size and, the level and small business share of Federal contracting dollars of the evaluated industries and sub-industries. SBA welcomes comments on these factors and/or suggestions on other factors that it should consider when evaluating or revising employee based size standards. SBA also seeks information on relevant data sources, other than what it uses, if available.

8. SBA gives equal weight to each of the five primary factors in all industries.

SBA seeks feedback on whether it should continue giving equal weight to each factor or whether it should give more weight to one or more factors for certain industries. Recommendations to weigh some factors more than others should include suggested weights for each factor along with supporting information.

9. For analytical simplicity and efficiency, in this proposed rule, SBA has refined its size standard methodology to obtain a single value as a proposed size standard instead of a range of values, as in its past size regulations. SBA welcomes any comments on this procedure and suggestions on alternative methods.

Public comments on the above issues are very valuable to SBA for validating its size standard methodology and its proposed size standards revisions in this proposed rule. This will help SBA to ensure that size standards reflect industry structure and Federal market conditions. Commenters addressing SBA’s proposed size standard revisions for a specific industry or a group of industries should include relevant data and/or other information supporting their comments. If comments relate to using size standards for Federal procurement programs, SBA suggests that commenters provide information on the size of contracts in their industries, the size of businesses that can undertake the contracts, startup costs, equipment and other asset requirements, the amount of subcontracting, other direct and indirect costs associated with the contracts, the use of mandatory sources of supply for products and services, and the degree to which contractors can mark up those costs.

**Compliance With Executive Orders 12866, 13563, 12988 and 13132, the Paperwork Reduction Act (44 U.S.C. Ch. 35) and the Regulatory Flexibility Act (5 U.S.C. 601–612)**

*Executive Order 12866*

The Office of Management and Budget (OMB) has determined that this proposed rule is a significant regulatory action for purposes of Executive Order 12866. Accordingly, in the next section SBA provides a Regulatory Impact Analysis of this proposed rule. However, this rule is not a “major rule” under the Congressional Review Act, 5 U.S.C. 800.

*Regulatory Impact Analysis*

1. Is there a need for the regulatory action?

SBA believes that the proposed size standards revisions in this proposed rule will better reflect the economic

characteristics of small businesses and the Federal government marketplace in the affected industries and. SBA’s mission is to aid and assist small businesses through a variety of financial, procurement, business development, and advocacy programs. To determine the intended beneficiaries of these programs, SBA establishes distinct definitions of which businesses are deemed small businesses. The Small Business Act (15 U.S.C. 632(a)) delegates to SBA’s Administrator the responsibility for establishing small business definitions. The Act also requires that small business definitions vary to reflect industry differences. The Jobs Act also requires SBA to review all size standards and make necessary adjustments to reflect market conditions. The supplementary information section of this proposed rule explains SBA’s methodology for analyzing a size standard for a particular industry.

2. What are the potential benefits and costs of this regulatory action?

The most significant benefit to businesses obtaining small business status because of this proposed rule is gaining or retaining eligibility for Federal small business assistance programs. These include SBA’s financial assistance programs, economic injury disaster loans, and Federal procurement programs intended for small businesses. Federal procurement programs provide targeted opportunities for small businesses under SBA’s business development programs, such as 8(a), Small Disadvantaged Businesses (SDB), small businesses located in Historically Underutilized Business Zones (HUBZone), women-owned small businesses (WOSB), economically disadvantaged women-owned small businesses (EDWOSB), and service-disabled veteran-owned small businesses (SDVOSB). Federal agencies may also use SBA’s size standards for a variety of other regulatory and program purposes. These programs assist small businesses to become more knowledgeable, stable, and competitive. SBA estimates that in 209 industries for which it has proposed to increase size standards about 1,250 firms, not small under the existing size standards, will become small under the proposed size standards and therefore become eligible for these programs. That is about 0.4 percent of all firms classified as small under the current size standards in all industries reviewed in this proposed rule. If adopted as proposed, this will increase the small business share of total receipts in those industries from 26 percent to 29 percent.

Three groups will benefit from the proposed size standards revisions in this rule, if they are adopted as proposed: (1) Some businesses that are above the current size standards may gain small business status under the higher size standards, thereby enabling them to participate in Federal small business assistance programs; (2) growing small businesses that are close to exceeding the current size standards will be able to retain their small business status under the higher size standards, thereby enabling them to continue their participation in the programs; and (3) Federal agencies will have a larger pool of small businesses from which to draw for their small business procurement programs.

SBA estimates that firms gaining small business status under the proposed size standards could receive Federal contracts totaling \$170 million to \$175 million annually under SBA's small business, 8(a), SDB, HUBZone, WOSB, EDWOSB, and SDVOSB Programs, and other unrestricted procurements. The added competition for many of these procurements can also result in lower prices to the Government for procurements reserved for small businesses, but SBA cannot quantify this benefit.

Under SBA's 7(a) and 504 Loan Programs, based on the fiscal years 2010–2012 data, SBA estimates up to about 25 SBA loans totaling about \$12.0 million could be made to these newly defined small businesses under the proposed size standards. Increasing the size standards will likely result in more small business guaranteed loans to businesses in these industries, but it is impractical to try to estimate exactly the number and total amount of loans. There are two reasons for this: (1) Under the Jobs Act, SBA can now guarantee substantially larger loans than in the past; and (2) as described above, the Jobs Act established a higher alternative size standard (\$15 million in tangible net worth and \$5 million in net income after income taxes) for business concerns that do not meet the size standards for their industry. Therefore, SBA finds it difficult to quantify the actual impact of these proposed size standards on its 7(a) and 504 Loan Programs.

Newly defined small businesses will also benefit from SBA's Economic Injury Disaster Loan (EIDL) Program. Since this program is contingent on the occurrence and severity of a disaster in the future, SBA cannot make a meaningful estimate of this impact.

In addition, newly defined small businesses will also benefit through reduced fees, less paperwork, and fewer

compliance requirements that are available to small businesses through Federal government.

To the extent that those 1,250 newly defined additional small firms could become active in Federal procurement programs, the proposed changes to size standards, if adopted, may entail some additional administrative costs to the government as a result of more businesses being eligible for Federal small business programs. For example, there will be more firms seeking SBA's guaranteed loans, more firms eligible for enrollment in the System of Award Management (SAM) database, and more firms seeking certification as 8(a) or HUBZone firms or qualifying for small business, WOSB, EDWOSB, SDVOSB, and SDB status. Among those newly defined small businesses seeking SBA's assistance, there could be some additional costs associated with compliance and verification of small business status and protests of small business status. However, SBA believes that these added administrative costs will be minimal because mechanisms are already in place to handle these requirements.

Additionally, Federal government contracts may have higher costs. With a greater number of businesses defined as small, Federal agencies may choose to set aside more contracts for competition among small businesses only rather than using full and open competition. The movement from unrestricted to small business set-aside contracting might result in competition among fewer total bidders, although there will be more small businesses eligible to submit offers. However, the additional costs associated with fewer bidders are expected to be minor since, by law, procurements may be set aside for small businesses or reserved for the 8(a), HUBZone, WOSB, EDWOSB, or SDVOSB Programs only if awards are expected to be made at fair and reasonable prices. In addition, there may be higher costs when more full and open contracts are awarded to HUBZone businesses that receive price evaluation preferences.

The proposed size standards revisions, if adopted, may have some distributional effects among large and small businesses. Although SBA cannot estimate with certainty the actual outcome of the gains and losses among small and large businesses, it can identify several probable impacts. There may be a transfer of some Federal contracts to small businesses from large businesses. Large businesses may have fewer Federal contract opportunities as Federal agencies decide to set aside more contracts for small businesses. In

addition, some Federal contracts may be awarded to HUBZone concerns instead of large businesses since these firms may be eligible for a price evaluation preference for contracts when they compete on a full and open basis.

Similarly, some businesses defined small under the current size standards may obtain fewer Federal contracts due to the increased competition from more businesses defined as small under the proposed size standards. This transfer may be offset by a greater number of Federal procurements set aside for all small businesses. The number of newly defined and expanding small businesses that are willing and able to sell to the Federal Government will limit the potential transfer of contracts from large and currently defined small businesses. SBA cannot estimate the potential distributional impacts of these transfers with any degree of precision.

The proposed revisions to the existing size standards for 210 industries in Sector 31–33 are consistent with SBA's statutory mandate to assist small business. This regulatory action promotes the Administration's objectives. One of SBA's goals in support of the Administration's objectives is to help individual small businesses succeed through fair and equitable access to capital and credit, Government contracts, and management and technical assistance. Reviewing and modifying size standards, when appropriate, ensures that intended beneficiaries have access to small business programs designed to assist them.

#### *Executive Order 13563*

Descriptions of the need for this regulatory action and benefits and costs associated with this action including possible distributional impacts that relate to Executive Order 13563 are included above in the Regulatory Impact Analysis under Executive Order 12866, above.

In an effort to engage interested parties in this action, SBA has presented its size standards methodology (discussed above under Supplementary Information) to various industry associations and trade groups. SBA also met with a number of industry groups and individual businesses to get their feedback on its methodology and other size standards issues. In addition, SBA presented its size standards methodology to businesses in 13 cities in the U.S. and sought their input as part of Jobs Act tours. The presentation also included information on the latest status of the comprehensive size standards review and on how interested

parties can provide SBA with input and feedback on size standards review.

Additionally, SBA sent letters to the Directors of the Offices of Small and Disadvantaged Business Utilization (OSDBU) at several Federal agencies with considerable procurement responsibilities requesting their feedback on how the agencies use SBA's size standards and whether current size standards meet their programmatic needs (both procurement and non-procurement). SBA gave appropriate consideration to all input, suggestions, recommendations, and relevant information obtained from industry groups, individual businesses, and Federal agencies in preparing this proposed rule.

The review of size standards in industries covered in this proposed rule is consistent with Executive Order 13563, Section 6, calling for retrospective analyses of existing rules. The last comprehensive review of size standards occurred during the late 1970s and early 1980s. Since then, except for periodic adjustments for monetary based size standards, most reviews of size standards were limited to a few specific industries in response to requests from the public and Federal agencies. The majority of employee based size standards, including those in NAICS Sector 31–33, have not been reviewed since they were first established. SBA recognizes that changes in industry structure and the Federal marketplace over time have rendered existing size standards for some industries no longer supportable by current data. Accordingly, in 2007, SBA began a comprehensive review of its size standards to ensure that existing size standards have supportable bases and to revise them when necessary. In addition, the Jobs Act requires SBA to conduct a detailed review of all size standards and to make appropriate adjustments to reflect market conditions. Specifically, the Jobs Act requires SBA to conduct a detailed review of at least one-third of all size standards during every 18-month period from the date of its enactment and do a complete review of all size standards not less frequently than once every 5 years thereafter.

#### *Executive Order 12988*

This action meets applicable standards set forth in Sections 3(a) and 3(b)(2) of Executive Order 12988, Civil Justice Reform, to minimize litigation, eliminate ambiguity, and reduce burden. The action does not have retroactive or preemptive effect.

#### *Executive Order 13132*

For purposes of Executive Order 13132, SBA has determined that this proposed rule will not have substantial, direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government. Therefore, SBA has determined that this proposed rule has no federalism implications warranting preparation of a federalism assessment.

#### *Paperwork Reduction Act*

For the purpose of the Paperwork Reduction Act, 44 U.S.C. Ch. 35, SBA has determined that this proposed rule will not impose any new reporting or record keeping requirements.

#### *Initial Regulatory Flexibility Analysis*

Under the Regulatory Flexibility Act (RFA), this proposed rule, if adopted, may have a significant impact on a substantial number of small businesses in the industries and sub-industries covered by this rule. As described above, this rule may affect small businesses seeking Federal contracts, loans under SBA's 7(a), 504 and Economic Injury Disaster Loan Programs, and assistance under other Federal small business programs.

Immediately below, SBA sets forth an initial regulatory flexibility analysis (IRFA) of this proposed rule addressing the following questions: (1) What are the need for and objective of the rule? (2) What are SBA's description and estimate of the number of small businesses to which the rule will apply? (3) What are the projected reporting, record keeping, and other compliance requirements of the rule? (4) What are the relevant Federal rules that may duplicate, overlap, or conflict with the rule? and (5) What alternatives will allow the Agency to accomplish its regulatory objectives while minimizing the impact on small businesses?

1. What are the need for and objective of the rule?

Changes in industry structure, technological changes, productivity growth, mergers and acquisitions, and updated industry definitions have changed the structure of many industries reviewed in this proposed rule. Such changes can be sufficient to support revisions to current size standards for some industries. Based on the analysis of the latest data available, SBA believes that the revised standards in this proposed rule more appropriately reflect the size of businesses that need Federal assistance.

The Jobs Act also requires SBA to review all size standards and make necessary adjustments to reflect market conditions.

2. What are SBA's description and estimate of the number of small businesses to which the rule will apply?

If the proposed rule is adopted in its present form, SBA estimates that about 1,250 additional firms will become small because of increased size standards 209 industries in NAICS Sector 31–33. That represents 0.4 percent of total firms that are small under current size standards in all industries in that Sector. This will result in an increase in the small business share of total industry receipts in Sector 31–33 from 26 percent under the current size standards to 29 percent under the proposed size standards. The proposed size standards, if adopted, will enable more small businesses to retain their small business status for a longer period. Many firms may have lost their eligibility and find it difficult to compete at current size standards with companies that are significantly larger than they are. SBA believes the competitive impact will be positive for existing small businesses and for those that exceed the size standards but are on the very low end of those that are not small. They might otherwise be called or referred to as mid-sized businesses, although SBA only defines what is small; other entities are other than small.

3. What are the projected reporting, recordkeeping and other compliance requirements of the rule?

The proposed size standard changes impose no additional reporting or recordkeeping requirements on small businesses. However, qualifying for Federal procurement and a number of other programs requires that businesses register in the SAM database and certify in SAM that they are small at least once annually. Therefore, businesses opting to participate in those programs must comply with SAM requirements. However, there are no costs associated with SAM registration or certification. Changing size standards alters the access to SBA's programs that assist small businesses, but does not impose a regulatory burden because they neither regulate nor control business behavior.

4. What are the relevant Federal rules, which may duplicate, overlap or conflict with the rule?

Under § 3(a)(2)(C) of the Small Business Act, 15 U.S.C. 632(a)(2)(c), Federal agencies must use SBA's size standards to define a small business,

unless specifically authorized by statute to do otherwise. In 1995, SBA published in the **Federal Register** a list of statutory and regulatory size standards that identified the application of SBA's size standards as well as other size standards used by Federal agencies (60 FR 57988 (November 24, 1995)). SBA is not aware of any Federal rule that would duplicate or conflict with establishing size standards.

However, the Small Business Act and SBA's regulations allow Federal agencies to develop different size standards if they believe that SBA's size standards are not appropriate for their programs, with the approval of SBA's Administrator (13 CFR 121.903). The Regulatory Flexibility Act authorizes an Agency to establish an alternative small business definition, after consultation with the Office of Advocacy of the U.S. Small Business Administration (5 U.S.C. 601(3)).

5. What alternatives will allow the Agency to accomplish its regulatory objectives while minimizing the impact on small entities?

By law, SBA is required to develop numerical size standards for establishing eligibility for Federal small business assistance programs. Other than varying size standards by industry and changing the size measures, no practical alternative exists to the systems of numerical size standards.

**List of Subjects in 13 CFR Part 121**

Administrative practice and procedure, Government procurement, Government property, Grant programs—business, Individuals with disabilities, Loan programs—business, Reporting and recordkeeping requirements, Small businesses.

For the reasons set forth in the preamble, SBA proposes to amend part 13 CFR part 121 as follows:

**PART 121—SMALL BUSINESS SIZE REGULATIONS**

■ 1. The authority citation for part 121 continues to read as follows:

**Authority:** 15 U.S.C. 632, 634(b)(6), 662, and 694a(9).

■ 2. In § 121.201, amend the table “Small Business Size Standards by NAICS Industry” as follows:

- a. Revise the entries for “311111”, “311211”, “311221”, “311314”, “311340”, “311351”, “311352”, “311411”, “311412”, “311421”, “311422”, “311423”, “311511”, “311512”, “311513”, “311514”, “311520”, “311611”, “311612”, “311613”, “311615”, “311710”, “311812”, “311813”, “311821”, “311824”, “311830”, “311911”, “311919”, “311920”, “311930”, “311941”, “312111”, “312112”, “312113”, “312120”, “312130”, “312140”, “312230”, “313110”, “313230”, “314110”, “314120”, “315110”, “315190”, “315210”, “315220”, “315240”, “315280”, “316992”, “321212”, “321213”, “321219”, “321911”, “321991”, “322121”, “322130”, “322211”, “322219”, “322220”, “322230”, “322291”, “323117”, “324110”, “324191”, “325194”, “325199”, “325211”, “325312”, “325320”, “325411”, “325412”, “325413”, “325414”, “325510”, “325611”, “325612”, “325613”, “325620”, “325992”, “326111”, “326112”, “326113”, “326122”, “326140”, “326150”, “326160”, “326191”, “326211”, “326220”, “326291”, “327110”, “327212”, “327213”,

- “327215”, “327310”, “327332”, “327410”, “327420”, “327910”, “327993”, “331110”, “331315”, “331511”, “331512”, “332111”, “332112”, “332215”, “332216”, “332311”, “332313”, “332321”, “332410”, “332420”, “332431”, “332510”, “332911”, “332912”, “332913”, “332919”, “332991”, “332992”, “333111”, “333112”, “333120”, “333132”, “333242”, “333244”, “333415”, “333611”, “333612”, “333613”, “333618”, “333911”, “333912”, “333913”, “333921”, “333923”, “333992”, “333995”, “333996”, “334111”, “334112”, “334210”, “334220”, “334412”, “334413”, “334417”, “334418”, “334510”, “334511”, “334513”, “334514”, “334515”, “334516”, “334517”, “334614”, “335110”, “335121”, “335210”, “335221”, “335222”, “335224”, “335228”, “335312”, “335313”, “335911”, “335932”, “336111”, “336112”, “336120”, “336212”, “336213”, “336214”, “336310”, “336320”, “336330”, “336340”, “336350”, “336360”, “336370”, “336390”, “336412”, “336413”, “336414”, “336415”, “336510”, “336611”, “336612”, “336991”, “336992”, “336999”, “337110”, “337121”, “337122”, “337124”, “337125”, “337211”, “337214”, “337910”, “337920”, “339112”, “339113”, “339114”, “339115”, “339920”, “339940”, “339992”, “339993”, and “339995”.

■ b. Revise footnotes 3, 4, 5, and 7. The revisions read as follows:

**§ 121.201 What size standards has SBA identified by North American Industry Classification System codes?**

\* \* \* \* \*

**SMALL BUSINESS SIZE STANDARDS BY NAICS INDUSTRY**

NAICS codes	NAICS U.S. industry title	Size standards in millions of dollars	Size standards in number of employees
311111	Dog and Cat Food Manufacturing		1,000
311211	Flour Milling		1,000
311221	Wet Corn Milling		1,250
311314	Cane Sugar Manufacturing		1,000
311340	Nonchocolate Confectionery Manufacturing		1,000
311351	Chocolate and Confectionery Manufacturing from Cacao Beans		1,250
311352	Confectionery Manufacturing from Purchased Chocolate		1,000
311411	Frozen Fruit, Juice, and Vegetable Manufacturing		1,000
311412	Frozen Specialty Food Manufacturing		1,250
311421	Fruit and Vegetable Canning <sup>3</sup>		31,000

## SMALL BUSINESS SIZE STANDARDS BY NAICS INDUSTRY—Continued

NAICS codes	NAICS U.S. industry title	Size standards in millions of dollars	Size standards in number of employees
311422	Specialty Canning		1,250

## Footnotes

\* \* \* \* \*

3. *NAICS code 311421*—For purposes of Government procurement for food canning and preserving, the standard of 500 employees excludes agricultural labor as defined in 3306(k) of the Internal Revenue Code, 26 U.S.C. 3306(k).

4. *NAICS code 324110*—To qualify as small for purposes of Government procurement, the petroleum refiner, including its affiliates, must be a concern that has no more than 1,500 employees OR no more than 200,000 barrels per calendar day total Operable Atmospheric Crude Oil Distillation capacity. Capacity includes all domestic and foreign affiliates, owned or leased facilities, and facilities under a processing agreement or an arrangement such as an exchange agreement or a throughput.

To qualify under the capacity size standard, the firm, together with its affiliates, must be primarily engaged in refining crude petroleum into refined petroleum products. A firm's "primary industry" is determined in accordance with 13 CFR 121.107.

5. *NAICS code 326211*—For Government procurement, a firm is small for bidding on a contract for pneumatic tires within Census NAICS Product Classification codes 3262111 and 3262113, provided that:

(a) The value of tires within Census NAICS Product Classification codes 3262113 which it manufactured in the United States during the previous calendar year is more than 50 percent of the value of its total worldwide manufacture,

(b) The value of pneumatic tires within Census NAICS Product Classification codes 3262113 comprising its total worldwide manufacture during the preceding calendar year was less than 5 percent of the value of

all such tires manufactured in the United States during that period, and

(c) The value of the principal product which it manufactured or otherwise produced, or sold worldwide during the preceding calendar year is less than 10 percent of the total value of such products manufactured or otherwise produced or sold in the United States during that period.

\* \* \* \* \*

7. *NAICS code 336413*—Contracts for the rebuilding or overhaul of aircraft ground support equipment on a contract basis are classified under NAICS code 336413.

\* \* \* \* \*

Proclamation 9163—National Grandparents Day, 2014

Presidential Determination No. 2014–14 of September 5, 2014—

Continuation of the Exercise of Certain Authorities Under the Trading With the Enemy Act

---

**Presidential Documents**

---

**Title 3—****Proclamation 9163 of September 5, 2014****The President****National Grandparents Day, 2014****By the President of the United States of America****A Proclamation**

Each year, we pause to salute the grandmothers and grandfathers who strengthen our families and shape our Nation. Through decades of hard work, they have broken down barriers and blazed pathways for the generations that followed, and they continue to provide inspiration and support to their children and grandchildren. On National Grandparents Day, we honor the anchors of our families and recognize the immeasurable ways they enrich our lives.

With grit and determination, our grandparents have built better lives for their loved ones and a better future for our country. From battlefields to factory floors, their relentless pursuit of progress has created new opportunities and made America more equal and more just. They have ushered in revolutionary advances in science and technology, putting us at the forefront of innovation. And they have shared in some of life's most cherished memories—from small moments to personal milestones—and been a source of comfort in difficult times.

Across our country, grandparents continue to contribute to their families and communities in countless ways. They volunteer in their neighborhoods, and for more than 5 million grandchildren, they serve as the head of household, providing unconditional love and support. Their tenacious spirit, commitment to family, and sense of service remind us that after a lifetime of hard work, they deserve to retire with security and dignity.

Today, we pay tribute to our grandparents and all the older Americans who have reached across generations and played an important role in our lives. With profound gratitude, we celebrate all they have accomplished and given to our Nation.

NOW, THEREFORE, I, BARACK OBAMA, President of the United States of America, by virtue of the authority vested in me by the Constitution and the laws of the United States, do hereby proclaim September 7, 2014, as National Grandparents Day. I call upon all Americans to take the time to honor their own grandparents and those in their community.

IN WITNESS WHEREOF, I have hereunto set my hand this fifth day of September, in the year of our Lord two thousand fourteen, and of the Independence of the United States of America the two hundred and thirty-ninth.

A handwritten signature in black ink, appearing to be "Barack Obama", written in a cursive style.

## Presidential Documents

Presidential Determination No. 2014–14 of September 5, 2014

### Continuation of the Exercise of Certain Authorities Under the Trading With the Enemy Act

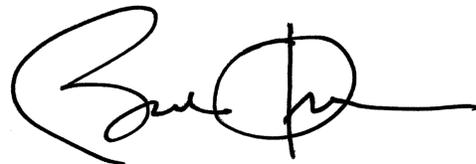

#### Memorandum for the Secretary of State [and] the Secretary of the Treasury

Under section 101(b) of Public Law 95–223 (91 Stat. 1625; 50 U.S.C. App. 5(b) note), and a previous determination on September 12, 2013 (78 *FR* 57225, September 17, 2013), the exercise of certain authorities under the Trading With the Enemy Act is scheduled to terminate on September 14, 2014.

I hereby determine that the continuation for 1 year of the exercise of those authorities with respect to Cuba is in the national interest of the United States.

Therefore, consistent with the authority vested in me by section 101(b) of Public Law 95–223, I continue for 1 year, until September 14, 2015, the exercise of those authorities with respect to Cuba, as implemented by the Cuban Assets Control Regulations, 31 C.F.R. Part 515.

The Secretary of the Treasury is authorized and directed to publish this determination in the *Federal Register*.

THE WHITE HOUSE,  
Washington, September 5, 2014

**Public Laws Electronic Notification Service (PENS)**

---

**PENS** is a free electronic mail notification service of newly

enacted public laws. To subscribe, go to <http://listserv.gsa.gov/archives/publaws-l.html>

**Note:** This service is strictly for E-mail notification of new laws. The text of laws is not available through this service. **PENS** cannot respond to specific inquiries sent to this address.
