Advantages: Targeting the PH domain improves specificity against Akt kinase in comparison to inhibitors of the ATP domain which typically are unspecific.

Government-Owned Inventions; Availability for Licensing

AGENCY: National Institutes of Health, Public Health Service, HHS.

ACTION: Notice.

SUMMARY: The inventions listed below are owned by an agency of the U.S. Government and are available for licensing in the U.S. in accordance with 35 U.S.C. 201–202 to achieve expeditious commercialization of results of federally-funded research and development. Foreign patent applications are filed on selected inventions to extend market coverage for companies and may also be available for licensing.

APPLICATIONS: Licensing information and copies of the U.S. patent applications listed below may be obtained by writing to the indicated licensing contact at the Office of Technology Transfer, National Institutes of Health, 6011 Executive Boulevard, Suite 325, Rockville, Maryland 20852–3804; telephone: 301/496–7057; fax: 301/402–0220. A signed Confidential Disclosure Agreement will be required to receive copies of the patent applications.

Spontaneously Transformed Mouse Epithelial Cancer Cell Lines Serving as Mouse Models: A New Model for Cancer Research

Description of Invention: Investigators at the NIH have created a collection of 45 mouse epithelial cancer cell lines derived from six organs: Bladder, cervix, colon, lung, kidney, and mammary glands. These cell lines were obtained from spontaneously transformed primary cell cultures without genetic, viral or chemical manipulation so they can serve as mouse models for studying the natural process of oncogenesis.

The cell lines were characterized cytogenetically during their transformation from normal to spontaneously immortalized and were found to recapitulate many of the changes observed in human cancer cells such as the deregulation of oncogenes (Myc, Mdm2) and tumor suppressor genes (Cdkn4a/Ink4a/p16, Rb).

Carcinomas that arise from the epithelial cells lining organs lead to the most common cancers in humans.

However, research on cellular transformation has largely relied on fibroblast cells which are not of epithelial origin and therefore, may not reflect the changes that lead to epithelial oncogenesis. The availability of these mouse epithelial cancer cell lines should allow for a more accurate analysis of this process.

Applications: These cell lines serve as “ideal” murine tumor models as they show evidence of progression, permitting analysis of the genetic and biological changes observed in the equivalent human carcinomas and associated with tumor progression. Their tumor histology is comparable to human cancers.

The cell lines have unique properties that make them suitable for study of the following:

• Unlimited replicative potential.
• Exhibit tumorigenic potential and EMT (Epithelial Mesenchymal Transition).
• Exhibit high degree of chromosome instability (chromosome rearrangements, amplifications) in regions orthologous to those altered in human cancers.
• Use in mapping mouse geneshomologous to human cancer genes and for the study of the effects of deregulation of cancer associated genes, through silencing or overexpression.
• For use in gene expression studies of tumor progression, comparing profiles to human cancers involving the same tissue types.
• Use as experimental controls in the analysis of oncogene signaling pathways.
• Use in the studying telomerase pathway regulation (200-fold expression difference between cell lines).
• Use of mouse as model of epithelial carcinomas and specifically cancers of the bladder, cervix, colon, lung, mammarys and kidney cancers.
• These mouse models serve as vehicles to test the efficacy of new therapies, targeting specific targets associated with the transformation of six different mouse epithelial tissues.
that have been implicated in the predisposition of endocrine tumors. An endocrine tumor is a growth that affects the parts of the body that secrete hormones. Because an endocrine tumor arises from cells that produce hormones, the tumor itself can produce hormones and cause serious illness.

The tumor samples made available herein contain deletions in the cyclic nucleotide phosphodiesterase (PDE) PDE7A or PDE8B genes that impair PDE function and are characterized by high sensitivity to changes in cAMP levels. Commercially, phosphodiesterase inhibitors are widely used in the treatment of various disorders, including asthma, pulmonary hypertension, and erectile dysfunction, suggesting a potential utility for these tissues in a wide range of investigations.

Applications: Useful in the investigation of the mechanisms of phosphodiesterase inhibition.

Akt-Ser473 Phosphorylation as a Marker for Predicting Taxane Chemotherapy Outcome

Description of Invention: Over the past decades, taxanes such as paclitaxel and docetaxel have emerged as effective chemotherapy agents for breast cancer and other malignancies. Taxanes are effective in many patients, however, not all patients benefit from this type of chemotherapy. A significant need remains for a means of predicting clinical outcome from taxane-based chemotherapy.

Akt, a serine/threonine kinase that can block apoptosis, has been implicated in the regulation of microtubule dynamics and organization. Akt phosphorylation and its transducing downstream events play a central role in cell survival and cell cycle progression at the G2/M transition. Paclitaxel or docetaxel inhibits Akt-Ser473 phosphorylation (pAkt) and induces mitotic arrest. Therefore, taxanes may cause more damage to tumor cells that are dependent on pAkt for survival and cell cycle progression, significantly impacting treatment outcome.

Researchers at the National Cancer Institute, NIH, have identified pAkt as having predictive significance for paclitaxel chemotherapy outcome in patients with early stage breast cancer. The researchers have developed an immunohistochemistry method for determining pAkt status with appropriate controls for assay performance and cutoff for pAkt positivity. They also discovered methods of correlating pAkt expression with clinical outcome (disease-free survival and overall survival). pAkt is a novel predictive marker of taxane chemotherapy, and can be applied to indicate which patients should receive taxane-based chemotherapy.

Applications: A Kit for identifying pAkt-positive tumors in surgical tumor specimens or tumor biopsies prior to treatment (adjuvant, neoadjuvant therapy or therapy for metastatic disease); and methods for predicting clinical outcome from taxane chemotherapy.

Advantages: pAkt is a useful clinical predictive marker to determine which patients should or should not receive taxane-based chemotherapy for cancer. Determining pAkt status would allow patients with pAkt-positive tumors to elect taxane therapy for whom are likely to benefit, and allow patients with pAkt-negative tumors for whom are unlikely to benefit to be spared from taxane therapy as well as toxicity, and earlier use of other therapies that could be more effective. The application of this invention may potentially reduce the cost of cancer care.
